# Introduction

ALP (A Latin Parser) is a syntactic parser for a small subset of classical Latin. How small the subset is (or how large, size lying in the beholder's eye), can be guessed through a quick perusal of the test files (included in this document), i.e. the collections of sentences that ALP is able to deal with, i.e. to parse. We do not think that ALP can be described as a toy parser, a mere sketch of what could be done on a larger scale (see for instance Covington 2003). A toy system is seldom extensible without a major revision of the very framework it is based on. That is not the case with ALP, as we will attempt to show.

ALP is a true parser, i.e. it delves into the surface strings looking for deep syntactic structure, which means here predicate-argument pairings, which it delivers according to a canonical order that is fully independent of the linearity of the sentences it deals with.

It is worth stressing that this endeavour amounts to more than simple tagging (the assignment of tags associated in a lexicon with the surface elements) followed by the limited amount of surface structure that can be built on the basis of sequences of tags (a good example of what can be achieved with these limited means is Koster 2005).

The argument structure referred to above is not limited to noun phrases (nps), prepositional phrases (pps) and the like, but includes clauses, which can exhibit the complex structure associated with full independent sentences. In a word, we have to do with true parsing.

Of course, the linearity of discourse will be seen to be preserved in the *wordlist* associated with the surface string, but is also taken into account in assessing the weighting assigned to a given parse, its preference ranking. As a matter of fact, most reasonably complex sentences will receive more than one parse (i.e. will be ambiguous with respect to the grammar embodied in the parser, although they may appear – and be – fully unambiguous as utterances, if we leave aside the body of utterances used as grammatical examples or illustratory material for schoolbooks, even if borrowed from the classical writers, precisely because they are deprived of their context of utterance). The weighting procedure aims at keeping only the most promising parses (or in presenting them first to the user, which amounts to the same). A weighting procedure is an essential part of a parser, even if it is often missing.

Latin exhibits a relatively free word order, and is therefore not likely to be amenable to top-down parsing, which is based on the checking of structural hypotheses derived from the grammar (and specifying a given left-to-right ordering) by confronting their expectations with what is found in the string submitted to analysis.

A better candidate is provided by a bottom-up parser, which looks at what it has under hand (the string with its given word order) and tries to put it together somehow on the basis of the structural descriptions the grammar holds for higher elements (for example, putting together a noun and an adjective sharing gender, number and case to produce a np which will be able to fill in a syntactic slot, let's say subject if the case is nominative - or accusative in an infinitival clause - and number is compatible with that of the VP of which it is supposed to provide the subject).

It is such a bottom-up parser that ALP implements, but in a way that takes full advantage of the 'facilities' offered by Prolog<sup>1</sup>, which are in fact the very mechanisms that Prolog is built on, I mean UNIFICATION and BACKTRACKING.

Before moving on to a discussion of those two basic mechanisms, a short and drastically oriented introduction to Prolog as a programming language may be in order<sup>2</sup>.

In Prolog we describe a *world*, very often a *micro-world*, the *objects* that populate that world and the *relations* that obtain between them. We do this by means of *facts* and *rules*. In our case the micro-world is a subset of classical Latin, the facts are mainly to be found in the lexicon and the rules in the grammar.

Note that the notion of the distinction between facts and rules running parallel to that between lexicon and grammar is very much a simplification. It can be argued that the description of *multi-word units* that we need for parsing is much nearer to grammar rules than to standard lexical entries. I have attempted to show elsewhere that most multi-word units, unless they are completely frozen, are best captured by rules that look very much like standard grammar rules, except that they contain lexical material that restricts the openness of the purely structural requirements of standard grammar rules (see Michiels 2016a).

Facts in Prolog are like records in a standard data base, but in a much freer format. Rules have conditions of the *if-and-only-if* type, and can lead to the production of new facts, which are then added to the database of facts Prolog is working with and which aims at capturing the basic facts and relations of the world being described.

Once the description of the *world*, its inhabitants and properties, is embodied in a Prolog program, we can submit *queries*, i.e. ask questions. A Prolog query (a question set to the Prolog engine) will be interpreted in the following way: is this provable? If the query contains *variables*, it will involve finding values for the variables that make the query true. So, by the side of very simple queries, which look like queries on a standard data base, we can formulate queries of a much more complex form, asking Prolog to enquire whether the object we propose can be admitted as a new inhabitant of our world (can be *proved* to be such an inhabitant), and what values need to be assigned to the variables in the query to make it so.

In our case (once the parser and the grammatical and lexical resources it draws on have been entered as a Prolog program), we can submit a string to Prolog, and ask whether that string can be read as a Latin sentence (i.e. can the string be *proved* to be a Latin sentence?). We can leave as variables to be instantiated (i.e. given a value) what will turn out to be the parse, i.e. the structural assignments that explain why the string is in fact the embodiment of one or more Latin sentences (there will be more than one *proof* if the string is ambiguous with respect to the grammar and lexicon in use).

To sum up, the variables to be instantiated will be bits of the structural make-up of the sentence, under the structural assignment that made that string a Latin sentence, according to the grammar and lexicon embodied in the Prolog database built as a result of running the program. This data base is partly static (standard lexical entries), but mainly dynamic – applying the rules yields new structures. When Prolog has found a structural description (i.e. a parse) that covers the whole input

---

1 We use SWI-Prolog, a long-standing high-quality free Prolog. A suitable installation file (i.e. geared towards the OS one is using) can be downloaded from the SWI-Prolog website. See Wielemaker 2003 for an overview.

2 Among the most useful introductions to Prolog is certainly to be ranked *The Art of Prolog* by Leon Sterling and Ehud Shapiro, Second Ed. The MIT Press and [https://cliplab.org/~logalg/doc/The\\_Art\\_of\\_Prolog.pdf](https://cliplab.org/~logalg/doc/The_Art_of_Prolog.pdf) On Prolog and NLP : Fernando Pereira and Stuart Shieber, *Prolog and Natural-Language Analysis*, Digital Edition, <http://www.mtome.com/Publications/PNLA/prolog-digital.pdf>

string, it has found one way of making the string a Latin sentence. It is then ready to start all over again, and find the other possible ways of parsing the string that make it a Latin sentence (and thereby dealing with ambiguous sentences, ambiguous with respect to the grammar and lexicon embodied in the Prolog program, which, as we have said, may or may not reflect perceived ambiguity when the sentence is replaced in its discursive context).

Let us not be mean, let's give at least a toy example... Suppose we feed Prolog the following program:

```
noun(regina, agreement(case:nominative,gender:feminine, number:singular)).
noun(reginam,agreement(case:accusative,gender:feminine, number:singular)).
noun(reginae, agreement(case:nominative,gender:feminine, number:plural)).
noun(reginas,agreement(case:accusative,gender:feminine, number:plural)).

noun(fatum, agreement(case:nominative,gender:neuter, number:singular)).
noun(fatum,agreement(case:accusative,gender:neuter, number:singular)).
noun(fata, agreement(case:nominative,gender:neuter, number:plural)).
noun(fata,agreement(case:accusative,gender:neuter, number:plural)).

adjective(clara, agreement(case:nominative,gender:feminine, number:singular)).
adjective(claram,agreement(case:accusative,gender:feminine, number:singular)).
adjective(clarae, agreement(case:nominative,gender:feminine, number:plural)).
adjective(claras,agreement(case:accusative,gender:feminine, number:plural)).

adjective(clarum, agreement(case:nominative,gender:neuter, number:singular)).
adjective(clarum,agreement(case:accusative,gender:neuter, number:singular)).
adjective(clara, agreement(case:nominative,gender:neuter, number:plural)).
adjective(clara,agreement(case:accusative,gender:neuter, number:plural)).
```

The above are *facts*, the first type of Prolog *clause*. They are made up of a *functor* (here, *noun* or *adjective*) with a given *arity*, i.e. number of elements within its domain, known as *arguments* (in this case, 2). In our bundle of facts, the first arg(ument) is *atomic* (to simplify drastically: a word or a number) and the second takes the form of a functor with its own arg(ument)s. The functor is *agreement*, and the args take the form of *features*, i.e. pairs of *feature name: feature value*, both atomic in this case (e.g. *gender:neuter*).

We add a *rule* to our program (the second form of Prolog clause). It reads as follows :

```
pair(First, Second,Agreement):-
( (adjective(First,Agreement),noun(Second,Agreement)) ;
  (adjective(Second,Agreement),noun(First,Agreement)) ).
```

A few words of explanation are in order:

*pair(First, Second, Agreement):-*

% means: we can conclude (regard it as a *fact*)  
% that we have a *pair* of two members, *First* and *Second*  
% (these are variables, opening with a capital letter as variables do in Prolog),  
% exhibiting an agreement triplet referred to as *Agreement*.  
% Note that the latter too is a variable, and that the variable name  
% gives no information to Prolog as to its contents – *X* or *Y* would have conveyed as much  
% information, the program writer being the only one who knows that he means this variable  
% to stand for an agreement triplet such as *agreement(case:accusative,gender:neuter, number:plural)*

% *if and only if* (that's the meaning of ':-')

( *(adjective(First,Agreement),noun(Second,Agreement)) ;*  
*(adjective(Second,Agreement),noun(First,Agreement))* ).

% we have (i.e. in our data base) a pair adjective-noun,  
% in either order (the operator 'OR' is written ';' in Prolog)  
% (bracketing being necessary because each branch of the alternative is made up of *two* clauses)

% and the two agreement triplets are UNIFIABLE (here unification boils down to identity – see  
% below for a fuller treatment).

Once the program has been fed into the Prolog database, we can enter queries such as

a) (query type: is this true?) e.g.     *pair(clara,regina,\_)*.     Answer should be 'true'  
   *pair(fata, clara,\_)*.     Answer should be 'true'  
   *pair(reginas, clara,\_)*.     Answer should be 'false'

In the above queries, the underline (    ) lets Prolog know that we are not interested in the value assigned to the argument, in this case the agreement triplet.

b) (query type: what values should the variables get in order to make this true ?)  
e.g. *pair(clara,regina,Accord)*.  
*Accord* will be instantiated to *agreement(case:nominative,gender:feminine, number:singular)*.

Try to guess what the following query is likely to yield:

*pair(Premier,Second,agreement(case:nominative,\_,\_))*.

The answer being given on the next page, pause a few seconds before moving on.

The answer consists in a series of pairs ranging over the available vocabulary, all in the nominative case. The 'false' at the end of the list means that there are no more answers, as far as Prolog knows (i.e. has been told).

Note that the order in which the answers are given reflects the order Prolog follows in exploring the data base; in fact, it reads the way we do: from left to right and from top to bottom (to get the answers at the terminal we should press the ';' key after each pair).

```
Premier = clara,  
Second = regina ;  
Premier = clarae,  
Second = reginae ;  
Premier = clarum,  
Second = fatum ;  
Premier = clara,  
Second = fata ;  
Premier = regina,  
Second = clara ;  
Premier = reginae,  
Second = clarae ;  
Premier = fatum,  
Second = clarum ;  
Premier = fata,  
Second = clara ;  
false.
```

**UNIFICATION** is a simple and powerful mechanism. It accomplishes two things : verifying structural compatibility and retrieving and assigning information. In ALP we make use of a feature-unification algorithm, which turns straight Prolog unification into a less rigid mechanism but is firmly based on standard unification all the same (see Gal et al. 1991).

*Feature* here is not to be understood as restricted to *atomic binary feature* such as the *singular-plural* pair to capture *number*. A feature as we understand it in ALP has an atomic feature *name* all right (such as *number*) but can take as *value* any structure recognizable by Prolog, i.e. any Prolog *term*. Such structures include *lists* and *trees*, and well-nigh anything the linguist can dream of ever wanting to use.

Let us give a simple example, not related to linguistics or to ALP. Let's build a structure whose functor-name is *suite* and whose argument is a three-element *list*.

*Lists* are sequences of *elements* enclosed in square brackets. The *elements* can be *atomic*, or themselves be *structures*, *lists*, or any other *Prolog term* (a *term* being anything Prolog recognizes as its own, remember). Examples are:

|  |              |
|--|--------------|
| <code>[albert,bernard,camille,didier, zedig]</code>                                | (atoms)      |
| <code>[Ten, Nine,One, Two, Three]</code>   | (variables)  |
| <code>[first(One,1,Next), [X,Y,z], A,B,C, [zedig], auteur(zedig, voltaire)]</code> | (complex)    |
| <code>[]</code>  | (empty list) |

Note that lists are explored by means of the operator '|', which divides the list into *Head* and *Tail*.

The *Head* is a list element, or several such elements, separated by commas, as are all list elements; the *Tail* is the remainder of the list, and is itself always a list.

Unification can be used to show '=' at work:

$$[a,b,C,d,e,f] = [A,B|Queue].$$

The unification of the two lists succeeds, with the following variable instantiations:

$$A=a, B=b, Queue=[C,d,e,f].$$

Examples of our *suite* structure would be

$$\begin{array}{l} suite([semel(One), bis(Two), ter(Three)]) \quad \text{and} \\ suite([semel(1), F, ter(3)]) \end{array}$$

Recall that variables in Prolog open with a capital letter, so that *One*, *Two*, *Three* and *F* are variables. If we use the operator for straight Prolog unification, which we have seen to be nothing else than the equal sign, we can write:

$$suite([semel(One), bis(Two), ter(Three)]) = suite([semel(1), F, ter(3)])$$

entering it as a Prolog *query*, i.e. asking Prolog to carry out the unification.

Unification will first check *structural compatibility*. We have two structures here whose functor is *suite* and whose argument is a list, so that they are compatible if the lists themselves are compatible. The *arity* of the lists is the same: 3 (recall that the arity is simply the number of constituents). The two lists will therefore be compatible if each of their elements is compatible. The first is a structure with functor *semel* and a single argument. So far so good, but the arguments must themselves be compatible, i.e. unifiable. This is the case (meaning: they ARE unifiable) because variables (and *One* is a variable) are unifiable with anything, therefore variable *One* is unifiable with the numeric atom found in the corresponding slot, i.e. *1*. The unification succeeds by giving the value *1* to the variable *One* (we say that *One* is *bound* or *instantiated* to *1*). In a similar way, in the second list element, the variable *F* will be bound to the structure *bis(Two)*, the variable *Two* continuing *unbound*. In the third list element, *Three* will be bound to *3*. The resulting structure (i.e. the result of the unification process) will be:

$$suite([semel(1), bis(Two), ter(3)]).$$

In ALP unification is used to associate morphological variants with lexical items, to retrieve the argument structure of predicates within their entries, to ensure gender, case, number compatibility, and well-nigh everything else. Matching the argument list of a predicate will simply mean going down the list, picking each element and trying to unify it with what we find in the string submitted to analysis. Unification, with the added flexibility of feature unification as implemented in ALP, can deal with the assignment of decorated tree structures to utterances, i.e. parsing. The decoration will be mainly lexical (the words as leaves), but any type of added information (e.g. semantic) can be envisaged, as long as it is computable (for instance, in ALP, the weight assigned to each parse, which leads to the selection of the best parse or parses).

**BACKTRACKING** plays an important part in the tracking of all the possible solutions to a given problem. Seeing that language (especially with respect to a given grammar) is highly ambiguous,

both globally (at sentence level) and locally (within the structure of phrases that will be included at a higher level, where further choices will operate), it is essential for the parser to be able to come up with all the solutions licensed by the grammar it embodies.

Backtracking is the mechanism by which Prolog keeps track of every single choice point in the search tree. Whenever a goal fails, Prolog backtracks to the last choice it made in its attempt to solve the goal, and chooses another branch of the search tree, if there is any that is still unexplored. If all fail, Prolog moves up one step further up the tree, and tries another branch up there. While doing this, it also uninstantiates any variable that got instantiated while Prolog was exploring the branch that led to failure.

In order to find all possible solutions, we can simply store the current solution, and force failure, and thereby force backtracking to occur. As a matter of fact, Prolog itself provides what are known as *second-order predicates* to build a list (including a sorted list) of all solutions. In ALP we use sorting on the weight in order to get the best solutions first, if there are more than one.

One might wonder what kind of profit to expect from a Latin parser. After all, we do not need such a tool as a first step towards machine translation, the texts we are interested in here (classical Latin texts) having been translated and retranslated, commented and over-commented.

The profit we can derive is directly linked to the absence of pressure of any kind. We do not NEED such a parser, so that we can concentrate on what a parser can teach us about language. To be usable as the basis for a parser, a grammar needs a degree of explicitness which forces it to come to grips with a good number of issues that are likely to have been considered irrelevant or to have been relegated to stylistics, i.e. quirks and idiosyncrasies left over to expressive power and the like. A major issue that has to be dealt with is the amount of freedom in word order – what are the limits that need to come to be part of an algorithmic treatment? How does syntax interact with semantics and pragmatics, in a way that can be shown to improve coverage, i.e. increase the part that can be dealt with algorithmically?

The development of a parser for Latin does not pursue any practical aim. It can be conceived as a contribution to the study of the language, in a spirit of free enquiry, which also means freedom from any pressure that does not directly derive from the subject under scrutiny.

The above considerations militate in favour of a parser whose design keeps grammar and parsing algorithm as separate as possible. We achieve that aim by relying entirely on a *production system* as parsing algorithm. The production system is organized in *passes*. Each pass is implemented as a series of production rules which operate over and over again until they are unable to produce anything new, in which case they pass control over to the next pass.

The production rules are allowed to build structure on the basis of what is available to them. In the first pass, the lexical pass, the words in the text are paired with the information stored about them in the lexicon (we have seen that this is a matter of straight variable instantiation). When we claimed above that the reading of *fata* as an nominative case would lead to failure, we certainly did not mean that this happened at the lexical look-up stage, where there is absolutely no information available to reject the nominative case or prioritize the accusative. The information is simply stored and made available to the next pass (higher in the structure-building hierarchy).

The grammar passes will likewise proceed from simple structures to more complex ones that need the information provided by the simple ones. Again, all the production rules in a given pass are allowed to produce structure over and over again, until they have nothing to add at their level.

Let's look at a very simple production rule to be found in the first grammar pass, that for building one-word nps such as *rex* in *rex scribit epistulam*.

The comments included in the Prolog program provide basic information about the np building procedures :

The core NPS are assembled before the other NPs, for which they can serve as building blocks. There are indeed two passes for nps: *core* and *finite*. The core NPs are simple nps that do not involve predications, therefore no relatives, no arg-bearing nouns, just the simple buiding blocks: nouns as nps, names as nps, adj+n as np, and so on...

Each np is associated with an index which refers to the positions it spans in the input string. The index is useful to make sense of *gaps*, i.e. *traces* (*t* or *e* in syntactic parlance) 'left' by elements 'moved out of place' by 'transformations'. The quotes are meant to show distance with respect to the syntactic theory underlining such treatment.

But undoubtedly a similar treatment is needed. If the trace cannot be associated with the relative pronoun, and, via the relative, and more importantly, with the antecedent, all the controls we wish to perform, such as semantic controls on arg bearers, will prove impossible in relative clauses, to give one example.

We then proceed to the production rules for simple nps, and begin with nps consisting of a single noun. We give below the *lex* clause for our word *rex*

```
lex(rex, noun, [pos:noun, txt:rex, lex:rex, case:nom, gender:masc, class:common, number:sing, sem:[hum]]).
```

The relevant production rule is the following:

```
[core,np1] ->
[mapped(noun,[from:A,to:B|FS]),
 constraint([pos:noun,lex:Lex,class:common,sem:Sem,txt:Text,
            number:Nb,gender:G,case:C],FS),
 map(np,[pathlist:[p(A,B)],hp:[p(A,B)],index:i(p(A,B)),distance:[0],
          cat:np,sem:Sem,class:common,lextype:full,
          number:Nb,person:3,gender:G, type:core,lex:Lex,txt:Text,
          case:C,w:1]])].
```

Which basically means that if we have in our text (we have it *mapped* by a previous *production*), from position A to position B (remember that capitals are reserved for variables in Prolog – A and B are thus variables), an item that was placed in the noun box and is associated with *feature bundle* FS, then we can use the predicate **constraint** to check or retrieve information from that feature bundle: we need here a common noun, a full lexical item; we retrieve the information contained in the feature bundle regarding *number*, *gender*, *case*, *textual form* and *semantic class*: *sing*, *masc*, *nom*(inative), *rex*, *[hum]*. We can then allow the production rule to produce (via the predicate **map**) a record to be put into the np (noun phrase) box.

Such a box will include information about the path covered by the np, the head of such a path, the index in case we need it somewhere down in the structure-building process (for instance if *rex* was to be found to be the antecedent of a relative pronoun), the distance within the path (in case of non-contiguity of the constituents<sup>3</sup>), morphological and lexical information derived from the lexical

---

3 In the pretty-printed parses, we give the value of the 'distance' feature if it is greater than zero. It records the number of words that separate elements that are expected to be contiguous. For instance, in the parse of Martial's line *Aestivo serves ubi piscem tempore quaeris?*, *aestivo tempore* gets assigned the function of adjunct of time with a discontiguity value (distance) of 3, on account of the three words (*serves ubi piscem*) that separate the two constituents of the adjunct, *tempore* and its adjective *aestivo*. This information is likely to be of use in word order and stylistic research.

item. We add person (third person), a type (core np) and a weight (1).

This may seem to be a very heavy procedure just to account for what is dealt with in a couple of rewrite rules in a top-down or bottom-up parser, namely

$np \rightarrow n, n \rightarrow rex$       or       $rex \rightarrow n, n \rightarrow np$ .

But in fact all the other information we gather and transport via the production rules based on feature unification will prove to be useful or downright indispensable in any sophisticated parser designed for a nearly free order language such as Latin.

The important design decision is to select a process (such as the one embodied in production rules) that boils down to monotonous incrementation of the available information. This does not prevent us from using specifically designed algorithms for ancillary tasks.

In short, we try to combine a parsing algorithm that is reduced to monotonous structure incrementation through a production system with various procedures that compute the quality rating of the structures licensed by the grammar rules and the information embodied in the lexical items (for instance the argument structure of a predicate, which has predictive power on how the string elements need to be structured into phrases of various levels such as nps and clauses).

A linguist will surely find that there is a huge distance between the type of grammar he is used to writing and the one he is confronted with in ALP. Well, there is a price to pay – an algorithm embodying a grammar cannot be a grammar written without an idea of how it is to be used in parsing. What we can attempt to do is to make the grammar as *declarative* as possible, i.e. as independent as we can make it from issues of control, of how it is to be used, in what order its rules are to be applied, where structures are to be stored, what should be done in case of failure, and the like. As soon as we attempt to go beyond toy systems, we have to dirty our hands a little and think about issues like the degree of freedom there really is in an 'order-free' language such as Latin, and what to do to assess the quality of the parses delivered by the system. The profit we will draw from such an effort is that we will increase explicitness, and have a much better idea of coverage, i.e. how much of the language can be captured by our rules.

Finally, is there nothing to be said *against* ALP as a parser for Latin? Well, there is one negative point, which, if we were parsing anything else but a dead language, would be rather devastating. The production system sketched here is *inefficient*<sup>4</sup> – its very monotony (it does one single thing: increase available information) is at that price.

We should bear in mind the reasons for which one may want to produce a Latin parser – I can see two main reasons only: teaching and research. The quicker the better shouldn't be our motto, surely.

A word about the format of ALP parses. Many scholars undoubtedly expect dependency tables or – in a much more readable format – dependency graphs, produced by a dependency grammar. We have opted for a constituency formalism resulting in parses as nested lists embodying the constituency relations<sup>5</sup>. But since the parses are in fact Prolog terms we are free to put in much more information than constituency relations alone. And we do not need to import code in order to produce readable parses, a simple pretty-printer can do the trick, and is freely adaptable.

---

<sup>4</sup> It would seem that at present a fifteen word limit should be imposed on strings to be parsed, unless time does not matter AT ALL, which is seldom the case...

<sup>5</sup> They can be adapted to *json* format, as can all Prolog terms.

Constituency and dependency grammars are known to be roughly equivalent. I think that whatever format we use for the parses should be free of the word order within the parsed sentence. Information about word order should obviously be preserved but need not be expressed by a corresponding order in the elements building up the parse tree or graph. Parse readability is much better if the parse tree is built around relations between clauses, and inside the clauses around the argbearers and their arguments, reserving for the periphery satellites of various types.

## **Positions**

(each article deserving a lengthy treatment)

\*\*\* an interesting parser is likely to be brittle (by 'interesting' I mean 'likely to reveal sth about the language it is a parser of') and rule-based (explicit and explainable rules) ;

\*\*\* a parser of a semi-free word order language such as classical Latin needs to be able to call on the following resources :

- a unification algorithm (indispensable in so far as it can be used both for checking and building structures of any depth and complexity)
- an automatic backtracking procedure (to clear unfruitful paths and the assignments performed along the way) ; works in tandem with unification
- a blackboard (area of memory where the parser can write and erase at will) ;

\*\*\* a parser needs a weighting procedure to rank candidate parses ; parses may be licit with respect to the grammar and lexis provided but be very unlikely in terms of acceptable reading proposals (so-called spurious ambiguities) ;

\*\*\* a parser needs to call on semantic and knowledge-of-the-world features associated with the lexical entries it makes use of.

## Lexical look-up

We come back in more detail (and apologizing for repetition) to the *lexical look-up* process, which associates information to be found in the lexicon with the words encountered in the text:

```
[lex,words] ->[recorded(pos,position(A,B,Word),_),  
               lex(Word,Box,FS),  
               map(Box,[from:A,to:B|FS])].
```

In this unusual construction, where left of the arrow ( $\rightarrow$ ) we find information that does not lead to any action, we accordingly need to concentrate our attention on what follows the arrow.

Structurally, it is a list. The elements it contains (three) are actions to be performed, i.e. calls to Prolog predicates defined somewhere in the program (facts or rules).

The first such call (to the *recorded* clause) specifies that a feature (the second argument of the *recorded* clause) must have been stored in the data base in the box specified as first argument (*pos* here, a *box* being a named bundle of records), corresponding, unsurprisingly, to the lexical item's *pos* (position).

The feature in question (*position(A,B,Word)*) is a three-arg structure: the start and end positions of the item in the sentence are recorded in the first two arguments, the variables *A* and *B* pointing to the beginning and end positions of the word in the wordlist corresponding to the sentence. The *Word* variable refers to the word found between these two positions in the wordlist representing the string.

For instance, if the sentence is '*Habent sua fata libelli.*' (the first example sentence in our test file, credits to Terentianus Maurus), the corresponding wordlist will be *[habent,sua,fata,libelli]* and *fata*, for instance, will be found to occupy the third position, i.e. from 2 to 3 (the count beginning at 0). As a matter of fact, the production of the wordlist corresponding to the input string will already have inserted the positions in the resulting wordlist (as well as specifying the end position by means of the *endpos* feature):

```
[0/habent,1/sua,2/fata,3/libelli,endpos(4)]
```

In this instance, the positions of the word and the morphological variant will have been stored in a record belonging to the *pos* box ('position' records), yielding here, by instantiation: *position(2,3,fata)* (variable *A* being instantiated to 2, *B* to 3, and *Word* to *fata*).

We then retrieve information on *fata* from the lexicon (*lex(Word,Box,FS)* (i.e. the set of *lex* clauses). The lookup (carried out by straight Prolog unification) yields two such Prolog clauses, one for nominative and one for accusative:

```
lex(fata, noun, [pos:noun, txt:fata, lex:fatum, case:nom, gender:neuter, class:common, number:pl, sem:[abstract]]).  
lex(fata, noun, [pos:noun, txt:fata, lex:fatum, case:acc, gender:neuter, class:common, number:pl, sem:[abstract]]).
```

the pattern being *lex(Textual\_form,Record\_Box\_in\_db,Feature\_List)*

The *lex* clauses have arity 3, i.e. three arguments: the first is the morphological variant itself (*fata*), the second the POS (Part of Speech, this time) and the third is a list of features, with information on part of speech, text form, lexeme, case, gender, number, class, and a list of semantic features, a single one in this case, namely 'abstract'.

The three arguments will instantiate the variables *Word*, *Box* and *FS*:

Word = *fata*, Box = noun, and FS will be instantiated to the first feature list (that for *fata* as nominative: [pos:noun, txt:fata, lex:fatum, case:nom, gender:neuter, class:common, number:pl, sem:[abstract]])

Note that such an assignment will eventually lead to failure (its fate...), *fata* being an accusative in our sentence; as will be explained in the next section, backtracking will occur, and the second feature list will come to bind the variable FS.

We then record the information (ending the look-up procedure) in a box (i.e. a collection of records) whose name is that of the POS, i.e. in this case 'noun' : map(Box,[from:A,to:B|FS]).

The feature bundle FS ([pos:noun, txt:fata, lex:fatum, case:nom, gender:neuter, class:common, number:pl, sem:[abstract]] ) will come to be included in a list whose first two elements will be the positions within which the item was found in the user's text. Variable binding will therefore yield:

*map(noun, [from:2, to:3, [pos:noun, txt:fata, lex:fatum, case:nom, gender:neuter, class:common, number:pl, sem:[abstract]]])*

The thing is obvious, but worth bearing in mind : lexical lookup has no prescience as to what the parser will retain and build into a parse and what it will reject as unusable for the parsing of a given sentence. Consider the very simple sentence *hunc librum legit*. Lexical lookup will pull out not three but five lex clauses, namely :

*lex(hunc, adj, [pos:adj, txt:hunc, lex:hic, gender:masc, type:tool, case:acc, number:sing]).*  
*lex(hunc, prdem, [pos:prdem, txt:hunc, lex:prdemaccmasc, gender:masc, person:3, sem:\_, case:acc, number:sing, function:[object, prep\_cplt, subject]]).*

*lex(librum, noun, [pos:noun, txt:librum, lex:liber, case:acc, gender:masc, class:common, ab:no, number:sing, sem:[thing, abstract]]).*

*lex(legit, v, [pos:v, class:tr\_cod, type:finite, lex:legere, voice:act, txt:legit, tense:perfect, kind:std, mood:indicative, number:sing, person:3]).*  
*lex(legit, v, [pos:v, class:tr\_cod, type:finite, lex:legere, voice:act, txt:legit, tense:present, kind:std, mood:indicative, number:sing, person:3]).*

Only one *hunc* will survive, the one where *hunc* is assigned *adj* as part of speech, because the *prdem* (demonstrative pronoun) reading will prove to be unusable in parsing the sentence. The two lex clauses for *legit* will both be retained, giving rise to two parses for the sentence, which will therefore be recognized as ambiguous on account of the double tense assignment (present vs perfect).

If the template for *legere* (templates are responsible for argument assignment, more on that below) had offered the possibility of assigning both a direct object and a complement of the object, we would have had a parse assigning the object function to the pronoun *hunc* and the function of complement of the object to *librum*, giving rise to an interpretation along the lines of *he reads/read this one as a book* (as if it were a book?). But the template for the sense of *legere* we are interested in here (the *legere* meaning *read* not *choose*) is simply :

*lexarg(legere,*  
    *arglist:[ws(lego\_read,tr\_cod,clause:[],mwuw:0,*  
        *args:[subject:[type:np,oblig:yes,constraints:[sem:[hum]]],*  
        *object:[type:np,oblig:no,constraints:[case:acc]]])].*

## ***ALP gets going parsing the simplest (?) ambiguous sentence***

We will feed ALP a complete sentence so as to get an opportunity to see it at work, and so gain a feeling of sympathy for a system willing to go through so many tricks just to parse a simple sentence.

So, let's see how ALP goes about parsing *Rex venit*.

The sentence in ASCII format (*Rex venit*.) is submitted first to a homemade version of the Prolog linereader, which turns it into the string *rex uenit*, taking care of decapitalization and changing *v* (*venit*) into standard *u* (*uenit*) and removing the final dot :

*rex uenit*

The WordList maker takes the two words to produce the list

*[0/rex,1/uenit,endpos(2)]*

at the same time storing the first two list elements into a storage space named *pos* (*pos* stands for positions) with the help of the predefined *recorda* predicate :

*recorda(pos,position(Pos,Posand1,NewHead),\_),*

thus storing in *pos* both *position(0,1,rex)* and *position(1,2,uenit)*

Running the *makelex.pl* program will have given rise to the following *lex* clauses of interest for our little sentence (they are housed in *wordforms*) :

*lex(rex, noun, [pos:noun, txt:rex, lex:rex, case:nom, gender:masc, class:common, ab:no, number:sing, sem:[hum]]).*

*lex(uenit, v, [pos:v, class:intr, type:finite, lex:uenire, voice:act, txt:uenit, tense:perfect, kind:std, mood:indicative, number:sing, person:3]).*

*lex(uenit, v, [pos:v, class:intr, type:finite, lex:uenire, voice:act, txt:uenit, tense:present, kind:std, mood:indicative, number:sing, person:3]).*

Note that there are two *lex* clauses for the word *uenit*, which is the source of the ambiguity : *uenit* is either *present* or *perfect* tense.

ALP proceeds by allowing different packets of rules to fire according to the stage it has reached in building the parse. The firing of a rule packet is guided by the following clause :

*run(Pass) :- [Pass,\_] ---> Condition\_Action,*  
*testexec(Condition\_Action),*  
*run(Pass).*

It should be noted that ALP grammar rules are built according to the format specified above, namely :

*[Pass,\_] ---> Condition\_Action*

where *Condition\_Action* is a list of Prolog goals. For instance, in the rule which we are going to use in a moment to take care of our two words, *rex* and *uenit*, namely :

```
[lex,words] --->[recorded(pos,position(A,B,Word),_),
                  lex(Word,Box,FS),
                  map(Box,[from:A,to:B|FS])].
```

The *Pass* variable is instantiated to *lex*, and the *Condition\_Action* list is instantiated to

```
[recorded(pos,position(A,B,Word),_),
  lex(Word,Box,FS),
  map(Box,[from:A,to:B|FS])].
```

This list is made up of three Prolog goals, which ALP will attempt to satisfy : the *recorded* goal will be satisfied if there is a record in the *pos* box which can be matched with the *position* structure, instantiating the variables *A*, *B* and *Word* ; the *lex* goal will then look for a match leading to the instantiation of *FS*, using the value of the variable *Word* which results from the instantiation just performed by *position(A,B,Word)*. The *map* goal will then be attempted with the instantiated variables. Such a goal list will be satisfied as many times as new information gets recorded by the predicate *map*, which is defined as follows :

```
map(Box,FS) :- not(recorded(Box,FS,_)), recorda(Box,FS,_).
               % the not recorded is essential for keeping track of a 'no new solution' situation
               % it enables the various runs to come to an end – see below
```

In other words, *map* will fail when it has no new information to store.

The *Condition\_Action* list is submitted to the *testexec* goal, which simply takes each element of the list in turn and executes it as a Prolog goal :

```
testexec([]).
testexec([First|Rest]) :-
    call(First),
    testexec(Rest).
```

In order to execute something as a Prolog goal, we simply pass it on as the argument of the predefined *call* predicate.

Note that the definition of the *run* predicate given above ends on a recursive call to itself. This ensures that all alternative ways of satisfying the goals executed by *testexec* are attempted ; but if we want the process to come to an end some time, we must ensure that the goal be allowed to fail. The failure is ensured by the condition on *map* : it cannot map what has already been mapped, so it will fail when it has nothing new to store.

Our *runs* begin with the lexical run, i.e. by running the *words* rule in the *lex* run :

```
runs :- run(lex).

[lex,words] --->[recorded(pos,position(A,B,Word),_),
                  lex(Word,Box,FS),
```

*map(Box,[from:A,to:B|FS])).*

A record (a feature bundle) is added to the data base in the box corresponding to the lexical item's POS (Part of Speech). The start and end positions of the item in the string are recorded in the first two features; the remaining features are read off the lexicon.

We have, in the *pos* box, the records

*position(0,1,rex)* and *position(1,2,uenit)*

and we have the above three *lex* clauses for *rex* and *uenit*.

The two words are *rex* and *uenit*, the two boxes are *noun* and *v* and the three *FS* (Feature Sets) are :

*[pos:noun, txt:rex, lex:rex, case:nom, gender:masc, class:common, ab:no, number:sing, sem:[hum]]*

for *rex*

and

*[pos:v, class:intr, type:finite, lex:uenire, voice:act, txt:uenit, tense:perfect, kind:std, mood:indicative, number:sing, person:3]*

and

*[pos:v, class:intr, type:finite, lex:uenire, voice:act, txt:uenit, tense:present, kind:std, mood:indicative, number:sing, person:3]*

for *uenit*

The *words* rule will fire repeatedly, and unification will ensure the 'copy' of the information. The *map* rule (which is simply *recorda*, i.e. a storing procedure) will fire with the following unifications for *map(Box,[from:A,to:B|FS])* :

*map(n,[from:0,to:1, pos:noun, txt:rex, lex:rex, case:nom, gender:masc, class:common, ab:no, number:sing, sem:[hum]])*

*map(v,[from:1, to:2, pos:v, class:intr, type:finite, lex:uenire, voice:act, txt:uenit, tense:perfect, kind:std, mood:indicative, number:sing, person:3])*

*map(v,[from:1, to:2, pos:v, class:intr, type:finite, lex:uenire, voice:act, txt:uenit, tense:present, kind:std, mood:indicative, number:sing, person:3])*

Remember that *|* is simply the list separator, and does not appear when the list is rebuilt.

We now have our two words recorded under their POS (Part of Speech).

*uenit*, being a *v* (verb) will fire a rule for building the verb group, firing which will happen when running the set of rules marked as *verb* , whose execution follows on that of *lex*.

*runs :- run(verb).*

```

[verb,vgl] --->
[ mapped(v,[from:B, to:C\FSI]),
  ifthen(constraint([gender:Gender],FSI),G=Gender), % we have a gender, we record it
                                                    % if we don't, we leave the G var a free var
                                                    % this prevents failure in the case of a gender check
  map(vgpos,[cat:vg,pathlist:[p(B,C)],hp:[p(B,C)], gender:G,w:0\FSI])).

```

Note that using *B* and *C* as variable names instead of whatever else (*A* and *B*, for instance) has no bearing whatsoever on the instantiations : the important thing is that they are variables ; the match with the information mapped by the *words* rule will be as follows :

*B* will be instantiated to 1 and *C* to 2 and *FSI* to, in turn,

```
[pos:v, class:intr, type:finite, lex:uenire, voice:act, txt:uenit, tense:perfect, kind:std, mood:indicative, number:sing, person:3]
```

and

```
[pos:v, class:intr, type:finite, lex:uenire, voice:act, txt:uenit, tense:present, kind:std, mood:indicative, number:sing, person:3]
```

Since we don't have a gender feature in *FSI*, the final mapping will be :

```
map(vgpos,[cat:vg,pathlist:[p(1,2)],hp:[p(1,2)], gender:G,w:0, pos:v, class:intr, type:finite, lex:uenire, voice:act, txt:uenit,
tense:perfect, kind:std, mood:indicative, number:sing, person:3] ).
```

and

```
map(vgpos,[cat:vg,pathlist:[p(1,2)],hp:[p(1,2)], gender:G,w:0, pos:v, class:intr, type:finite, lex:uenire, voice:act, txt:uenit,
tense:present, kind:std, mood:indicative, number:sing, person:3] ).
```

These mappings will go into the *vgpos* box, to be used by further ALP rules.

*Rex*, being a noun, will fire the simplest rule *np1* for noun phrase building,

```
runs :- run(core). % core nps
```

```
[core,np1] --->
```

```
[mapped(noun,[from:A,to:B|FS]),  
  constraint([lex:Lex,class:common,sem:Sem,txt:Text,  
             number:Nb,gender:G,case:C],FS),
```

```
ifthenelse(constraint([origin:adj],FS),  
  ( W is (0.5), Origin=adj),  
  ( W is 1,    Origin=noun)  
  ),      % nouns out of adjs have lighter weight
```

```
map(np,[pathlist:[p(A,B)],hp:[p(A,B)],index:i(p(A,B)),distance:[0],  
  cat:np,sem:Sem,class:common,lextype:full,origin:Origin,  
  number:Nb,person:3,gender:G, type:core,lex:Lex,txt:Text,  
  case:C,w:W,constituent_structure:Text])).
```

Recall that mapping the noun *rex* has led to A and B being instantiated to 0 and 1 and FS to

```
[pos:noun, txt:rex, lex:rex, case:nom, gender:masc, class:common, ab:no, number:sing, sem:[hum]]
```

The *constraint* predicate will lead to the following instantiations :

*lex* : *rex*, *class*:*common* (this is a check, since the variable is instantiated in the first arg of the *constraint* predicate), *sem* :*[hum]*, *txt*:*rex*, *number*:*sing*, *gender*:*masc*, *case*:*nom*.

Since there is no *origin* feature in FS, *W* (the weight) is set to 1 and *Origin* is instantiated to *noun*. The resulting mapping is thus the following :

```
map(np,[pathlist:[p(0,1)],hp:[p(0,1)],index:i(p(0,1)),distance:[0],  
  cat:np,sem:[hum],class:common,lextype:full,origin:noun,  
  number:sing,person:3,gender:masc, type:core,lex:rex,txt:rex,  
  case:nom,w:1,constituent_structure:rex])
```

The mapping is stored in the *np* box, to be used by further ALP rules.

We now come to the building of the whole predication (the whole clause, in this case the whole S as well, the whole sentence). Here (i.e. in this brief presentation) we have to drastically simplify the rule ALP is using, as most of the code does not concern such a simple clause as that embodied in *rex uenit*.

[finite,predbase] --->

```
[
  mapped(vg,FSverb),
  constraint([number:Nsubj,
    person:Psubj,
    type:finite,
    voice:Voice,
    mood:Mood,
    tense:Tense,
    pathlist:PathlistVerb,
    lex:Clex,
    w:WVerb],FSverb),

  lexarg(Clex,arglist:ArgList),
  pick(ws(Lex,_clause:Clause_Constraints,mwuw:MW,args:Args), ArgList,_),
```

.....

```
match_list(Args,TreeArgs,PathlistArgs,DistanceArgs,
  sujet([number:Nsubj,gender:_person:Psubj]),
  finite,
  gap:Gap,
  w:Weight,
  Int,
  PathlistVerb),
```

.....

```
map(pred,[cat:pred,
  type:finite,
  pathlist:NSortedF,
  distance:[Distance],
  illocutionary_force:Force,
  class:m,
  number:sing, % nber, gender, and person of the CLAUSE, not its subject
  person:3,vgperson:Psubj, % needed in imperative clauses of the first and second persons
  gender:neuter,
  mood:Mood,
  tense:Tense,
  polarity:Pol,
  argbound:no,
  gap:Gap,
  w:Wtot,
  add:Add,
  checkint:Interrogative,
  flagint:Flagint,
  constituent_structure:[illocutionary_force:Force,vg:FSverbfull|ST]]). % ST is the sorted list of arg fillers
```

Let's look at the top third :

```
mapped(vg,FSverb),
constraint([number:Nsubj,
           person:Psubj,
           type:finite,
           voice:Voice,
           mood:Mood,
           tense:Tense,
           pathlist:PathlistVerb,
           lex:Clex,
           w:Wverb],FSverb),
```

```
lexarg(Clex,arglist:ArgList),
pick(ws(Lex,_clause:Clause_Constraints,mwuw:MW,args:Args), ArgList,_),
```

We have two mapped *FSverb* we can retrieve, and we'll take the first here (the second will be used in a similar fashion when ALP looks for further instantiations) :

```
map(vgpos,[cat:vg,pathlist:[p(1,2)],hp:[p(1,2)], gender:G,w:0, pos:v, class:intr, type:finite, lex:uenire, voice:act, txt:uenit,
tense:perfect, kind:std, mood:indicative, number:sing, person:3] ).
```

The instantiation process carried out by *constraint* will yield the following :

*Nsubj* = sing, *Psubj* = 3, *Voice* = act, *Mood* = indicative, *Tense* = perfect,  
*PathlistVerb* = [p(1,2)], *Clex* = uenire, *Wverb* = 0.

We now turn to the *lexarg* goal ; it will fire with the instantiation for *Clex* which we have just retrieved :

```
lexarg(uenire, arglist:ArgList)
```

The match for such a goal is to be found in *frames.pl*, which ALP reads in before starting its dialogue with the user. *frames.pl* includes the following *lexarg* clause :

```
lexarg(uenire,
      arglist:[ws(uenio_come,intr,clause:[],mwuw:0,
                  args:[subject:[type:np,oblig:yes,constraints:[sem:[hum]]],
                        prep_cplt:[type:pp,oblig:no,constraints:[prep:or([ad,in]), case:acc]],
                        cplt:[type:np,oblig:no,constraints:[case:acc,sem:[city]]],
                        cplt:[type:pred,oblig:no,constraints:[type:nonfinite_i, mood:supine]] ])]).
```

which leads to the instantiation of variable *ArgList* to :

```
[ws(uenio_come,intr,clause:[],mwuw:0,
    args:[subject:[type:np,oblig:yes,constraints:[sem:[hum]]],
          prep_cplt:[type:pp,oblig:no,constraints:[prep:or([ad,in]), case:acc]],
          cplt:[type:np,oblig:no,constraints:[case:acc,sem:[city]]],
          cplt:[type:pred,oblig:no,constraints:[type:nonfinite_i, mood:supine]] ])]
```

Attention should be drawn to the *oblig* feature, which will prove to be important in the parsing of *rex uenit*, because the only arg in the arglist which will turn out instantiated is the subject, the only arg with *yes* as value for the *oblig* feature, the other args being all optional (*oblig:no*) and left uninstantiated in *rex uenit*.

The next goal is a call to the *pick* predicate :

```
pick(ws(Lex,_,clause:Clause_Constraints,mwu:MW,args:Args), ArgList,_),
```

which selects an arbitrary element in a list (and ends up selecting them all in turn when repeatedly reattempted) :

*% pick : non-deterministic selection in a list*

```
pick(A,[A|B],B).  
pick(A,[B|C],[B|D]) :- pick(A,C,D).
```

*Pick* selects either the head of the list (*A* in *[A|B]*), returning the remainder of the list (*B*) in its third arg (first clause in the definition of *pick*) or selects an element in the remainder of the list (*C*) (second defining clause).

If the second clause succeeds, the list returned as third argument is made up of the first element of the list passed as second argument (*B*, left untouched) and of the tail of the list, to wit *D*, i.e. what remains of *C* when *A* has been *picked* out of it.

In our case, *pick* has a single element that it can pick, the head of the list, the tail being the empty list (there is a single *ws* structure in *ArgList*). The instantiations will therefore be :

```
Lex = uenio_come,  
Clause_Constraints = [],  
MW = 0,  
Args = [subject:[type:np,oblig:yes,constraints:[sem:[hum]]],  
        prep_cplt:[type:pp,oblig:no,constraints:[prep:or([ad,in]), case:acc]],  
        cplt:[type:np,oblig:no,constraints:[case:acc,sem:[city]]],  
        cplt:[type:pred,oblig:no,constraints:[type:nonfinite_i, mood:supine]] ]
```

Our next goal belongs to the second block of the *predbase* rule, namely :

```
match_list(Args,TreeArgs,PathlistArgs,DistanceArgs,  
           sujet([number:Nsubj,gender:_person:Psubj]),  
           finite,  
           gap:Gap,  
           w:Weight,  
           Int,  
           PathlistVerb),
```

a call to the *match\_list* predicate with a number of arguments already instantiated, and others to be instantiated by executing the *match\_list* goal.

The instantiated arguments (instantiations carried out by the predicate *constraint* – see above) are the following :

*Nsubj* = *sing*, *Psubj* = 3, *PathlistVerb* = [*p*(1,2)]

and of course the instantiation of *Args* which we have just seen :

```
Args = [subject:[type:np,oblig:yes,constraints:[sem:[hum]]],  
        prep_cplt:[type:pp,oblig:no,constraints:[prep:or([ad,in]), case:acc]],  
        cplt:[type:np,oblig:no,constraints:[case:acc,sem:[city]]],  
        cplt:[type:pred,oblig:no,constraints:[type:nonfinite_i, mood:supine]] ].
```

The call to *match\_list* will therefore be :

```
match_list([subject:[type:np,oblig:yes,constraints:[sem:[hum]]],
           prep_cplt:[type:pp,oblig:no,constraints:[prep:or([ad,in]), case:acc]],
           cplt:[type:np,oblig:no,constraints:[case:acc,sem:[city]]],
           cplt:[type:pred,oblig:no,constraints:[type:nonfinite_i, mood:supine]] ],
           TreeArgs,
           PathlistArgs,
           DistanceArgs,
           sujet([number:sing,gender:_person:3]),
           finite,
           gap:Gap,
           w:Weight,
           Int,
           [p(1,2)]),
```

We can now look at the *match\_list* clause definition :

```
match_list([Function:Specs|RemainingArgs],
           [ArgTree|ArgTrees],
           [PathlistArg|PathlistArgs],
           [DistanceArg|DistanceArgs],
           sujet(SConstraints),
           ClauseType,
           gap:Gap,
           w:BW,
           Int,
           PathlistVerb) :-
    match(Function:Specs,ArgTree,SConstraints,PathlistArg,DistanceArg,ClauseType,gap:Gap1,w:W1,Int,PathlistVerb),
    match_list(RemainingArgs,ArgTrees,PathlistArgs,DistanceArgs,sujet(SConstraints),
              ClauseType,gap:Gap2,w:W,Int,PathlistVerb),
    % match all the other args on the arglist

% BW is W+W1,          % sum the weights
myplus(W,W1,BW),
```

*Match\_list* performs a call to *match* and then a recursive call to itself. Note that in the definition of *match\_list* the first argument is presented as a list whose head has been isolated by unification :

```
[Function:Specs|RemainingArgs] =
[subject:[type:np,oblig:yes,constraints:[sem:[hum]]],
 prep_cplt:[type:pp,oblig:no,constraints:[prep:or([ad,in]), case:acc]],
 cplt:[type:np,oblig:no,constraints:[case:acc,sem:[city]]],
 cplt:[type:pred,oblig:no,constraints:[type:nonfinite_i, mood:supine]] ]
```

will yield

```
Function : Specs = subject:[type:np,oblig:yes,constraints:[sem:[hum]]]
```

```
and RemainingArgs = [prep_cplt:[type:pp,oblig:no,constraints:[prep:or([ad,in]), case:acc]],
                    cplt:[type:np,oblig:no,constraints:[case:acc,sem:[city]]],
                    cplt:[type:pred,oblig:no,constraints:[type:nonfinite_i, mood:supine]]
```

(remember that the tail of a list is always a list)

so that the call to *match* will be :

```

match(subject:[type:np, oblig:yes, constraints:[sem:[hum]]] ,
      ArgTree,
      sujet([number:sing,gender:_ ,person:3]),
      PathlistArg,
      DistanceArg,
      ClauseType,
      gap:Gap1,
      w:W1,
      Int,
      [p(1,2)]).

```

There are a number of definitions for the *match* predicate. The one for a subject of a finite clause is the one that will be triggered here, on account of the first arg passed to *match*, which specifies that it is interested in the subject arg. I give it here in a simplified version :

```

match(subject:Specs,
      subject:OutSpecs,
      [number:Nsubj,gender:Gendersubj,person:Psubj], % information on the subject taken over from the verb
      PathlistArg,
      DistanceArg,
      finite, % finiteness implies that subject is in the nominative case
      gap:[],
      w:W,
      Int,
      PathlistVerb ) :-

constraint([type:T],Specs), % looking at the nature of the required filler : pred, np, etc.
constraint([constraints:C],Specs), % fishing out the constraints on the arg

mapped(T,FSSpecs), % check that we have the type of phrase needed for the arg

constraint([number:NumberinSpecs,gender:GenderinSpecs,case:nom,person:Psubj],FSSpecs),
      % retrieving gender and number from the proposed subject and requiring nominative

constraint(Cs,OutSpecs), % applying all other relevant constraints
constraint([pathlist:PathlistArg, distance:DistanceArg,w:W],OutSpecs). % adding to OutSpecs

```

Unification yields : *Specs* = [type:np, oblig:yes, constraints:[sem:[hum]]]

The first call to *constraint* will instantiate *T* to *np*, the second call *Cs* to [sem:[hum]]. ALP will call on *mapped* to find what is stored in the *T* , i.e. *np*, box (where *rex* is stored) and will be able to instantiate *FSSpecs* to

```

[pathlist:[p(0,1)],hp:[p(0,1)],index:i(p(0,1)),distance:[0],
 cat:np,sem:[hum],class:common,lextype:full,origin:noun,
 number:sing,person:3,gender:masc, type:core,lex:rex,txt:rex,
 case:nom,w:1,constituent_structure:rex]

```

The call to *constraint* that follows will unify *NumberinSpecs* to *sing*, *GenderinSpecs* to *masc* and *Psubj* to *3*.

The *Cs* constraints boil down to [sem:[hum]], as we have just seen. The next call to *constraint* projects it into the variable *OutSpecs*, and the last call to *constraint* adds the triplet [pathlist:PathlistArg, distance:DistanceArg,w:W], so that *OutSpecs* is unified to [sem:[hum],pathlist:PathlistArg, distance:DistanceArg,w:W].

But note that the various features constitutive of *FSSpecs* have all been instantiated in the call to

mapped, and are therefore available : *PathlistArg* is instantiated to  $[p(0,1)]$ , *DistanceArg* to  $[0]$  and *W* to *l*.

So *OutSpecs* is now instantiated to :  $[sem:[hum], pathlist:[p(0,1)], distance:[0], w:l]$ . This list of features is passed on to the caller of *match*, i.e. *match\_list*, in the pair *subject:OutSpecs* as the value of the variable *ArgTree* :

*subject* :  $[sem:[hum], pathlist:[p(0,1)], distance:[0], w:l]$

ALP will use this information in buiding the resulting parse tree.

In the meantime, *match\_list* will go on applying to the remaining args specified in the arglist of *uenire*, namely :

*prep\_cplt* :  $[type:pp, oblig:no, constraints:[prep:or([ad,in]), case:acc]]$ ,  
*cplt* :  $[type:np, oblig:no, constraints:[case:acc, sem:[city]]]$ ,  
*cplt* :  $[type:pred, oblig:no, constraints:[type:nonfinite_i, mood:supine]]$

We have already pointed out that they are all optional (*oblig:no*) and can therefore be satisfied without being instantiated at all :

% all arguments consumed or only optional args left unsatisfied

```
match_list([_:Specs|RemainingArgs],
  ArgTrees,
  PathlistArgs,
  DistanceArgs,
  sujet(SConstraints),
  ClauseType,
  gap:Gap,
  w:W,
  Int,PathlistVerb) :-
  constraint([oblig:no], Specs),
  match_list(RemainingArgs,
    ArgTrees,
    PathlistArgs,
    DistanceArgs,
    sujet(SConstraints),
    ClauseType,
    gap:Gap,
    w:W,
    Int,
    PathlistVerb).
```

*match\_list* applies to each argument in turn, each time reducing the length of the arg list it still has to deal with. When the list is empty, the following clause will apply :

*match\_list*([],[],[],[0],\_,\_,w:0,\_,\_).

*match\_list* is satisfied : nothing to match, nothing to return as instantiation.

We come to our final block in the *predbase* rule, the mapping of the whole clause :

```

map(pred,[cat:pred,
      type:finite,
      pathlist:NSortedF,
      distance:[Distance],
      illocutionary_force:Force,
      class:m,
      number:sing,           % nber, gender, and person of the CLAUSE, not its subject
      person:3,vgperson:Psubj, % needed in imperative clauses of the first and second persons
      gender:neuter,
      mood:Mood,
      tense:Tense,
      polarity:Pol,
      argbound:no,
      gap:Gap,
      w:Wtot,
      add:Add,
      checkint:Interrogative,
      flagint:Flagint,
      constituent_structure:[illocutionary_force:Force,vg:FSverbfull|ST]]). % ST is the sorted list of arg fillers

```

Lots of explanations and a good deal of code would be necessary to explain how all the features come to be instantiated. It is the value of the *constituent\_structure* feature that will get printed as raw parse and then as pretty-printed parse by ALP. The arg we have been looking at, the subject arg filled by *rex*, will be the only element constitutive of *ST*, the (here vacuously) sorted list of args.

The two parses produced by ALP for *rex uenit* are given below. The cpu time is that taken by the whole parsing procedure. The parses produced have equal weight (1). The only difference is in the tense assigned to *uenit* : *present* or *perfect*

```

[0/rex,1/uenit,endpos(2)]
cputime : 0.015625

```

```

# Parsing Issues

## Grammatical Sketch

The heart of the grammar implemented in ALP revolves around the *predicate* and its *arguments* building a *clause* (a grammatical clause, not to be confused with a Prolog clause). The clauses can be *finite* or *non-finite* (infinitive, participial) and can contain clauses as constituents. The arguments taking the form of *phrases* (adjective phrases, noun phrases, prepositional phrases) can also contain clauses, for instance under the guise of relative clauses attached to noun phrases. Recursivity is also to be found at the level of the phrases themselves, since a prepositional phrase is best defined as a preposition governing a noun phrase, and a noun phrase itself can contain prepositional phrases. The ease with which Prolog handles recursivity is a major pluspoint in its use in the implementation of a grammar for a natural language such as Latin.

The association of a predicate and its arguments is a matter for the lexicon to handle, but the description of the structural make-up of the arguments and the constraints imposed on them (e.g. semantic) must be such that the grammar can tackle them – the interaction between grammar and lexicon must be total, with no piece of information in either that the other cannot 'understand', i.e. register or make use of.

We will attempt to show this by looking at two lexical entries for verbs and the requirements that they impose on a grammar capable to match them.

The lexical entries are those for *obluiſcor* and *timeo*. We are not concerned here with the mechanisms building all their morphological variants, but with their argument list, which are housed in the relevant *lexarg* clauses:

```
% OBLUIŒSCI
% Non obliuſcar ſermones tuos - Pascal, M  morial.
% Oblita eſt periculi ancilla fortior dominis multis.
% Obluiſcitur rex reginam longas epiſtulas ſcripſiſſe ancillae Marci.

lexarg(obluiſci,
  arglist:[ws(obluiſcor_forget,tr_cod,clause:[],mwuw:0,
    args:[subject:[type:np,oblig:yes,constraints:[sem:[hum]]],
      object:[type:np,oblig:no,constraints:[case:or([acc,gen])]]]),
    ws(obluiſcor_forget_that,tr_inf,clause:[],mwuw:0,
      args:[subject:[type:np,oblig:yes,constraints:[sem:[hum]]],
        object:[type:pred,oblig:yes,constraints:[type:nonfinite]]])].
```

The *arglist* opens with an indication of the word sense being described; here we have two word senses, *forget* and *forget\_that*. The information that follows concerns the *category* (transitive verb with np object, transitive verb with clausal object), the *constraints* it imposes on the clause in which it fits (here, the empty list indicates that there are no such constraints), its *weight* as a multi-word unit (0, since it is not a mwu), and then the *arglist* proper, the feature whose name is *args* and whose value is a list of arguments.

We should emphasize that the members of the *arglist* need not be found in the string to be parsed in the order in which they appear in the *arglist* (a canonical order used for easier maintenance of the lexicon). As a matter of fact, in our second example for *obluiſcor* the genitive object precedes the subject, and in the first example (the one drawn from Pascal's M  morial), the subject does not

appear in the sentence at all, but is projected from the verb phrase (first person subject).

In the first wordsense recorded here, the args are subject and object, the first obligatory and the second optional (in which case it can be argued that it is mostly context-retrievable), and both structurally nps. The constraints on the subject are semantic (the subject must bear the feature +HUM), and the constraints on the object are case-related. The default cases are of course nominative for subject and accusative for object. But the object of *obliuiscor* can also be in the genitive case, so we need an OR-value for case: either accusative (as in the example from Pascal's Mémorial) or genitive (as in our second example).

In the second wordsense, the arglist specifies a clausal object, a non-finite clause (accusative cum infinitive), as in our third example.

We see thus that our grammar must be able to structurally characterize nps and assign them functions within the clause they operate in. They must also receive a semantic description, and have been assigned a case. The grammar must also deal with clauses in arg position, both finite and non-finite. For an example of a finite clause as arg we can turn to the entry for *timeo*:

```
% TIMERE
% Timeo Danaos etiam dona ferentes.
% Timeo amicis meis.
% Timeo ne veniant ad urbem capiendam.

lexarg(timere,
  arglist:[ws(timeo_fear,tr_cod,clause:[],mwuw:0,
    args:[subject:[type:np,oblig:yes,constraints:[sem:[hum]]],
      object:[type:np,oblig:yes,constraints:[case:acc]]]),

    ws(timeo_fear_for,tr_cod,clause:[],mwuw:0,
      args:[subject:[type:np,oblig:yes,constraints:[sem:[hum]]],
        object:[type:np,oblig:yes,constraints:[case:dat]]]),

    ws(timeo_fear_that,tr_cod,clause:[],mwuw:0,
      args:[subject:[type:np,oblig:yes,constraints:[sem:[hum]]],
        object:[type:pred,oblig:yes,
          constraints:[type:finite,mood:subjunctive, argbound:yes,subordinator:or([ne,ut])]]))].
```

In the case of *timeo*, we have three distinct word senses, each with its own arglist; we have a general *fear*, a *fear for* and a *fear that*. The constraints on the args have already been discussed, except for the new type of arg associated with *timeo* as *fear that*. The object is again a whole clause (type:pred), with its own list of constraints: it must be a *finite* clause, in the *subjunctive* mood, bound to that argument and opened with subordinator *ne* or *ut*. All requirements that the grammar must handle properly for the word sense to be captured.

The above examples give a very rough idea of the granularity problems that arise in the pairing of a lexicon (whose granularity should extend to the wordsense) with a grammar.

## Dealing with Multi-Word Units

Another relevant example is the treatment of multi-word units. First, it should be clear that the description we give in the lexicon must allow their insertion into the grammatical framework we are implementing. Second, if their behaviour is not constrained in any way that the grammar is able to capture, their being read as mwu's must be given priority over the readings where they are just standard grammatical strings, although the latter readings cannot be excluded.

Consider a simple mwu such as *res nouae* (revolution). Lewis and Short :

4. *Novae res*, new things, novelties: *nihil te ad me postea scripsisse demiror, praesertim tam novis rebus*, Cic. Fam. 7, 18, 4.

Also *subst.*: *nōvum*, i, n., a new thing, a novelty; *news*: *novum attulerint, quod fit nusquam gentium*, Plaut. Cas. prol. 70: *num quidnam inquit novi?* Cic. de Or. 2, 3, 13: *si quid novi vel sero invenissem*, Quint. 2, 5, 3.

*Plur.*: *novorum interpositione priora confundere*, Quint. 10, 3, 32; 8, 3, 60.

But, in gen., *novae res* signifies *political innovations, a revolution*: Q. *Servilius Ahala Sp. Maelium novis rebus studentem manu suā occidit*, Cic. Cat. 1, 1, 3: *rerum novarum causam quaerere*, id. Agr. 2, 33, 91: *plebes novarum rerum cupida*, Sall. C. 28, 4: *cuncta plebes novarum rerum studio Catilinae incepta probabat*, id. ib. 37, 1: *novarum rerum avidi*, id. J. 19, 1.

In a double sense: *Segulium neglegamus, qui res novas quaerit: non quo veterem comederit—nullam enim habuit—sed hanc ipsam recentem novam* devorārit, *innovations and new wealth*, Cic. Fam. 11, 21, 2.

We enter it in the lexicon as follows:

```
% RES NOVAE (revolution)
% cupiditate regni adductus novis rebus studebat (Caesar, De Bello Gallico, 1.9.3)
[core,np2aii] --->
[mapped(noun,[from:A, to:B|FSnoun]),
 mapped(adj,[from:X, to:Y|FSadj]),
 constraint([number:pl,gender:fem,case:Case,lex:res],FSnoun), % plural needed, of course
 constraint([number:pl,gender:fem,case:Case,lex:nous],FSadj),
 adjacent([p(A,B)],p(X,Y)), % adjacency required res nouae or nouae res
 append([p(A,B)],p(X,Y),Path),
 msort(Path, Sorted),
 map(np,[pathlist:Sorted,hp:[p(A,B)],index:i(p(A,B)),distance:[0],cat:np,class:common,sem:[abstract],
      number:pl,gender:fem,type:core,lex:res_nouae,lextype:full,
      case:Case,w:3])].
```

This entry specifies that the noun *res* and the adjective *nouae* should be adjacent (as opposed to the adjective-noun nexus, where the two elements can be separated from each other: *res inuenit nouas*, 'he found new things'). The number is not free either: it must be plural, as opposed to the unspecified number of a standard adjective-noun nexus: *noua res*, 'a new thing'). Third, of course, the lexemes are specific: the noun must be *res* and the adjective must be *nouus*. If the relevant constraints are satisfied, we build a standard np, to which we assign a specific semantics (standard *res* can be sem:[thing]) and a specific lexical value (*res\_nouae*). And of course we increase the weight assigned to the np. An np made up of a noun and an adjective will have weight 2 and the weight we assign to *res\_nouae* is 3.

Let's now consider a more complex mwu, i.e. one with wider, less local constraints.

```
% ALIQUEM/QUOD (NON) PILI FACERE
% Praetor non amabat milites nec faciebat pili cohortem.
```

```
lexarg(facere,
  arglist:[ws(mwu_non_pili_facio_not_give_a_damn_tr_cod_cplt,clause:[polarity:neg],mwuw:2,
    args:[subject:[type:np,oblig:yes,constraints:[sem:[hum]]],
          object:[type:np,oblig:yes,constraints:[case:acc]],
          object_cplt:[type:phrase,frozen:yes,oblig:yes,constraints:[lex:pili]]]),
```

Remember Catullus, 10, 12-14? *praesertim quibus esset irrumator / praetor, nec faceret pili cohortem*. (not least when said praetor was a fuckface / and didn't give a shit for his poor staffers. - translation Peter Green).

*Pili facere* needs to be inserted in a non-affirmative context (provided here by *nec*, but there are other ways of making a context non-affirmative, such as *quid obstat quominus/quid est causae quin*). We therefore introduce a clause-level constraint, on clause polarity: `clause:[polarity:neg]`. We give a bonus weight to the verb (2). The object complement is a phrase, quite frozen, and whose lexical specification goes down to the word-level: we need *pili*, nothing else will do (the lexicon has an entry for the relevant phrase, namely *string(phrase,[pili],[lex:pili,w:1])*).

A second example may be welcome. Consider the phrase *in sententiam alicuius pedibus ire*, follow sby's judgment, take sides with sby (in a vote). The relevant template is the following, associated with *eo* :

```
% MWU : in sententiam alicuius pedibus ire
ws(in_sententiam_alicuius_pedibus_eo_take_sides_with_IDIOM,intr,clause:[],mwuw:2,

args:[subject:[type:np,oblig:yes,constraints:[sem:[hum]]],
      prep_cplt:[type:pp,oblig:yes,constraints:[prep:in,lex:sententia,case:acc]],
      cplt:[type:np,oblig:yes,constraints:[case:abl,lex:pes,constituent_structure:pedibus]]]),

% the constraint on constituent_structure ensures the whole cplt boils down to 'pedibus'
```

The parse produced by ALP for the sentence *Silanus permotus oratione Caesaris pedibus in sententiam Neronis iturum se dixerat* (adapted from Sallust, Cat., 50, 4) is the following in pretty-printed format :

```
illocutionary_force:statement

## Linearity

Let us consider the *contiguity check* algorithm as an example. In Latin, elements that belong together need not be found side by side in the string. A standard example is the Vergilian *patulae recubans sub tegmine fagi*, where the adjective *patulae* belongs to the noun *fagi* (both singular, both feminine, both genitive – the agreement triplet that we require to hold on the adjective-noun nexus). If we allow elements belonging together to be dispersed in the string, we won't find it too difficult to account for the np, precisely on the basis of the triple agreement required on the adj+n group. But notice that there is nothing in the intervening material (*recubans sub tegmine*) that would offer a better link for the adjective *patulae*. Just as *fagi* is justifiable as genitive attached to *tegmine*, and *tegmine* as governed by *sub*, and *sub tegmine* as place adjunct for *recubans*, *patulae* is justifiable as adjective attached to *fagi* – there is no other attachment to compete with the one that involves non-contiguity between adjective and noun. The same applies to *nullum* and *officium* in *Nullum in illa trepidatione Antonius constantis ducis aut fortis militis officium omisit*<sup>6</sup>.

In the case of competing links we need to assess the weight to be attached to each link and select the heavier of two or the heaviest among more than two. How do we proceed?

The first thing to notice is that first and foremost we need to keep track of where each string element is to be found in the string. We have seen how to do this with the algorithm computing positions while turning the string into a *wordlist*.

Now, to be able to use that information the way we should, we need to keep track of the position of the material covered in the case of any structure that gets superimposed on lexical material. We store this information in the *path* feature. If, in *bonus rex scripsit epistulas malas*, we build a np to cover *bonus rex* and another one to cover *epistulas malas*, we need to record in the first np a path extending from position 0 (in front of *bonus*) to 2 (at the end of *rex*), and in the second np a path extending from 3 to 5.

We also need to be able to say where the head of a structure is to be found. In the case of our two nps, the head is the noun and we record positions 0 to 1 for the first head (*rex*) and 3 to 4 for the second (*epistulas*).

---

6 Tacitus, *Hitoriarum Liber III*, XVII, 1. The distance factor for the whole sentence is 13.

We can now discuss the algorithms relating to path, distance and contiguity. We go straight to the Prolog program, where the comments are supposed to do part of the job of explaining how the algorithms work. We add a few more comments to make the procedure as explicit as we can.

```
% these procedures examine which parts of the string are covered by various elements
% they are meant to measure properties like adjacency, contiguousness and distance
```

```
% the path is a list of p(X,Y) structures, where X and Y stand for positions in the string,
% as computed when the string is entered in and processed.
```

## FINDING A PATH THAT COVERS THE WHOLE SENTENCE

```
% all the words of a string must be used up for a parse to be considered valid for the string
% no gap left and the end of the sentence must have been reached :
```

```
path(0,Fin,Pathlist)
```

```
% Begin and End are the extremities of the Pathlist (0 and whatever fin(Fin) records)
```

The *fin(Fin)* predicate stores in the variable *Fin* the last position in the string. It is taken care of by the process turning the string into a wordlist.

The predicate *path* is defined as follows :

```
path(Begin,End,Pathlist):-
    pick(p(Begin,Next),Pathlist,RPaths),
    path(Next,End,RPaths).
```

```
path(E,E,[]).
```

The procedure applies recursively to its third argument. The second clause for the predicate (i.e. *path(E,E,[])*) gets us out of recursion: when all the elements have been picked out, we are left with an empty list (*[]*) whose beginning and end are the same (single variable *E*, the end of the path). More on this below.

As for *pick*, it is a three-arg procedure. It arbitrarily picks up an element (first arg) in a list (second arg) and returns what remains of the list once the selected element has been taken out (third arg). It can be defined as follows:

```
pick(H,[H|T],T).
pick(X,[H|T],[H|T1]) :- pick(X,T,T1).
```

In both *path* and *pick* use is made of the data structure *List* and the core of the procedure is recursive, i.e. calls on itself in its very definition. This is quite a standard way to proceed in Prolog. Lists are explorable by means of the operator '|', whose second argument, remember, is always a list. We can recur on that list until we are left with the empty list, which we use in a defining clause which gets us out of recursion. Consider *pick* in that light. We begin with the simplest case one can think of: picking an element out of a list is achieved by selecting the element which is easiest to grasp, i.e. the head of the list, the element to the left of the operator '|'. The element picked is thus *H*, and the remainder of the list, which is a list, is *T* (the tail of the list). But the element to be picked can be anywhere in the list; we can select it by picking it out of the remainder of the list, which is what the second defining clause says: leave the head(*H*) well alone, and pick your *X* element in the remainder of the list, *T*. The list you will get as a result of picking out element *X* out of tail *T* we will refer to with variable *T1*. Therefore the list that should be returned as result of the picking is head *H* and tail *T1*, that is to say *[H|T1]*. Here the end of recursion clause does not refer to the empty list, because there is nothing to pick in an empty list – we need at least one element, and the pattern *[H|T]* therefore applies to the list in the clause that gets us out of recursion, in this case the first one.

In *path*, however, we need to explore the whole length of the pathlist. We need to pick elements until we reach the very last position referred to as *End* in the first clause. At that juncture the Pathlist must be empty, and we get out of recursion by means of the second defining clause for *path*. The Begin and End point must

be the same, since we then start from the end-position of the very last element in the path. We stay put, having reached our goal. The path is really a path because we cannot pick a new element (a new p-structure) unless its beginning point corresponds to the endpoint of the preceding p-structure. Backtracking ensures that a path will be found if there is a path to be found, i.e. all the p-structures can be joined by sharing a position (endpoint of one is start of the following).

## ADJACENCY

% see nps with genitive np as subconstituent for an example of the relevance of such a procedure

% **strict**

% one pair in the first path has an end which corresponds to the beginning of a pair  
 % belonging to the second path, or the other way round

% [p(3,5), p(2,3)] and [p(5,6), p(6,8), p(8,9)] for instance

```
adjacent(PL1,PL2):- member(p(_,Y),PL1), member(p(Y,_),PL2),!.
adjacent(PL1,PL2):- member(p(_,Y),PL2), member(p(Y,_),PL1).
```

The member predicate is self-explanatory: member(Element, List) succeeds if Element is a member of List. It can be defined as follows:

```
member(H,[H|T]).           % the Head of a List is a member of that List
member(H,[_|T]) :- member(H,T). % if it's not the Head, it should be a member of the tail T
```

% **relaxed adjacency**

% a distance of 1 or 2 (in the case of relaxadjacent2) is allowed between the two corresponding pairs

```
relaxadjacent(PL1,PL2):- member(p(_,Y),PL1), member(p(X,_),PL2), succ(Y,X),!.
relaxadjacent(PL1,PL2):- member(p(_,Y),PL2), member(p(X,_),PL1), succ(Y,X).
```

```
relaxadjacent2(PL1,PL2):- member(p(_,A),PL1),
                           member(p(C,_),PL2),
                           succ(A,B),
                           succ(B,C),!.
```

```
relaxadjacent2(PL1,PL2):- member(p(_,A),PL2),
                           member(p(C,_),PL1),
                           succ(A,B),
                           succ(B,C).
```

The *succ* predicate gives the successor of an element in the list [0,1,2,3,4.....n], e.g. succ(3,4) succeeds while succ(4,3) and succ(3,5) fail.

Note that *succ* is a *pre-defined* predicate, i.e. it belongs to the Prolog programming language and need not be defined by the user, i.e. the Prolog programmer. We therefore give it no definition in these notes.

% relaxed adjacency with control on intervening elements

% with respect to POS:noun

% sometimes we have to check that no noun occurs in an interval  
 % as when we wish to relate the heads of nps linked by the cplt noun relation  
 % involving a genitive phrase  
 % *Marci servas amicos*  
 % *Marci* preferably linked with *servas* rather than with *amicos*:  
 % *putabas Marci servas amicos reginae amasse*

```
relaxedadjacent1_n(PL1,PL2,n):- member(p(_,Y),PL1), member(p(X,_),PL2),
```

```

succ(Y,X),
\+ mapped(noun,[from:Y,to:X|FSnoun])).

```

```

relaxedadjacent2_n(PL1,PL2,n):- member(p(_,A),PL1), member(p(C,_),PL2),
    succ(A,B),succ(B,C),
    \+ mapped(noun,[from:A,to:B|FSnoun1]),
    \+ mapped(noun,[from:B,to:C|FSnoun2])).

```

Notice the \+, which is used in Prolog for negation. \+mapped is used to indicate that no element of the box noun exists that covers the intervening element, i.e. that the intervening element is not a noun.

% with respect to CASE GENDER and NUMBER

```

% when we try to relate adj and noun
% we are not likely to be allowed to jump a noun with all the right properties in terms of
% case gender and number:
% putabas malas servas amicas reginae fuisse
% malas is not likely to link with amicas by 'jumping' servas
% in the code below we use the cut-fail pair ('!',fail). The cut ('!') prevents backtracking, so that the fail
% that follows cannot be undone; the predicate being defined fails if a noun is found where it shouldn't be.
% Both the cut and the predicate fail are pre-defined

```

```

relaxedadjacent1_cgn(PL1,PL2,Case,Gender,Nb):- member(p(_,Y),PL1), member(p(X,_),PL2),
    succ(Y,X),
    mapped(noun,[from:Y,to:X|FSnoun]),
    constraint([case:Case,gender:Gender,number:Nb],FSnoun),
    !, fail.

```

```

relaxedadjacent1_cgn(PL1,PL2,Case,Gender,Nb).

```

```

relaxedadjacent2_cgn(PL1,PL2,Case,Gender,Nb):- member(p(_,A),PL1), member(p(C,_),PL2),
    succ(A,B),succ(B,C),
    ( mapped(noun,[from:A,to:B|FSnoun1]),
      constraint([case:Case,gender:Gender,number:Nb],FSnoun1)) ;
    ( mapped(noun,[from:B,to:C|FSnoun2]),
      constraint([case:Case,gender:Gender,number:Nb],FSnoun2))),
    !, fail.

```

```

relaxedadjacent2_cgn(PL1,PL2,Case,Gender,Nb).

```

```

relaxedadjacent3_cgn(PL1,PL2,Case,Gender,Nb):- member(p(_,A),PL1), member(p(D,_),PL2),
    succ(A,B),succ(B,C),succ(C,D),
    ( mapped(noun,[from:A,to:B|FSnoun1]),
      constraint([case:Case,gender:Gender,number:Nb],FSnoun1)) ;
    ( mapped(noun,[from:B,to:C|FSnoun2]),
      constraint([case:Case,gender:Gender,number:Nb],FSnoun2));
    ( mapped(noun,[from:C,to:D|FSnoun3]),
      constraint([case:Case,gender:Gender,number:Nb],FSnoun3))),
    !, fail.

```

```

relaxedadjacent3_cgn(PL1,PL2,Case,Gender,Nb).

```

## PATH CONTIGUITY

The *contiguity* and *distance* predicates are meant to work on *sorted* paths.

A path can be sorted by the predefined predicate *msort*, which applies a merge sort on its first argument and returns the result of the sort in its second argument (with both arguments instantiated it can also be used, of course, to check that the instantiated second arg results from a mergesort performed on the first arg)

msort(UnsortedPath, SortedPath), e.g.

1 ?- msort([p(4,5),p(2,3),p(1,2)],Sorted).  
Sorted = [p(1, 2), p(2, 3), p(4, 5)].

% the various elements follow each other without leaving a gap

contiguous([]).  
contiguous([One]).

contiguous([p(X,Y),p(Y,Z)|Tail]):- contiguous([p(Y,Z)|Tail]).

In words : an empty list is contiguous, i.e. does not feature non-contiguity...

A one-element list does not feature non-contiguity either

If the first two elements in a list are contiguous (the extremity of the first being the start of the second), then if the list made up of the second element and the tail of the list (all the remaining elements) is also contiguous, then the whole list is contiguous.

% in *quasicontiguous* we allow one element to be out of place

quasicontiguous(L):- contiguous(L), !. % Qui peut le plus...

quasicontiguous(L):- pick(EI,L,L1), contiguous(L1).

The *quasicontiguous* predicate can be applied as a check on non-finite clause constituency when dealing with poetry. The structures building such a clause must be found together, with the exception of a single word. This relaxed check on contiguity allows the parsing of the Horatian *Me tabula sacer votiva paries indicat uvida suspendisse potenti vestimenta maris deo*, where *Me* belongs to the non-finite complement clause of *indicat*: *Me ... uvida suspendisse potenti vestimenta maris deo*.

## DISTANCE BETWEEN TWO PATHS

% we first determine the end points of the two paths

% we determine the order in which they appear

% and then the distance between extremity of the first one and start of the second

distance(Path1,Path2,Distance):- extremity(Path1,Ext1), extremity(Path2,Ext2),  
start(Path1,St1), start(Path2, St2),  
ifthenelse(Ext1 =< St2, % IF  
Distance is St2 – Ext1, % THEN  
Distance is St1 – Ext2). % ELSE

% *extremity*: last position in pathlist

% we select the very last position registered, i.e. the second element of the p(X,Y) structure that ends the  
% path

extremity(PathList, Ex):- last(PathList,p(\_,Ex)).

% (*last(List,Last)* is true if *Last* is the last element of *List*)

% *last*, although *pre-defined* (i.e. part of the Prolog language) can be re(?)defined as follows:

last([Last],Last). % Last is the last element of a list which does not contain anything else

last(\_|Tail,Last):- last(Tail,Last). % If there is more than a single element in the list, then Last is the  
% last element of the Tail of the list

% *start*: first position in a pathlist

% the first element of a list is easy to find by simple unification:  
% we select the first element of the relevant p structure

```
start([p(Start,_)|_],Start).
```

% precedes(Path1,Path2)  
% works on sorted paths

```
precedes(P1,P2):- extremity(P1,Extremity), start(P2,Start), Extremity =< Start.
```

Consider now the following line from Martial, 2.78:

*Aestivo serves ubi piscem tempore quaeris?* (You want to know where to keep fish in summertime?)

[0/aestiuo,1/serues,2/ubi,3/piscem,4/tempore,5/quaeris,endpos(6)]

        adj:aestiuus
```

Such a sentence seems to exhibit a completely free word order. But it suffices to run it through a string generator to come to realize that this is far from the case. A six-word sentence generates 6!, i.e. 720 strings, most of which are totally ungrammatical:

```
aestivo piscem quaeris serves tempore ubi .  
aestivo piscem quaeris serves ubi tempore .  
aestivo piscem quaeris tempore serves ubi .  
aestivo piscem quaeris tempore ubi serves .  
aestivo piscem quaeris ubi serves tempore .  
...  
aestivo tempore quaeris ubi serves piscem .  
aestivo tempore serves piscem quaeris ubi .  
...  
piscem quaeris tempore ubi aestivo serves .  
piscem quaeris tempore ubi serves aestivo .  
piscem quaeris ubi aestivo serves tempore .  
piscem quaeris ubi aestivo tempore serves .  
...  
quaeris piscem ubi aestivo serves tempore .  
quaeris piscem ubi aestivo tempore serves .  
quaeris piscem ubi serves aestivo tempore .  
...  
serves aestivo piscem quaeris tempore ubi .  
serves aestivo piscem quaeris ubi tempore .  
serves aestivo piscem tempore quaeris ubi .  
...  
tempore quaeris piscem aestivo ubi serves .  
tempore quaeris piscem serves aestivo ubi .  
tempore quaeris piscem serves ubi aestivo .  
...  
ubi aestivo quaeris piscem serves tempore .  
ubi aestivo quaeris piscem tempore serves .  
...  
ubi tempore serves quaeris aestivo piscem .  
ubi tempore serves quaeris piscem aestivo .
```

So, the task does not boil down to letting the 'anything goes' principle make havoc of Latin word order, but to open up the range of possible grammatical strings by relaxing the contiguity we expect structures to exhibit, while taking care not to allow the production of strings that would turn out to be impossibly ambiguous. The various path procedures enable us to contain freedom within reasonable (i.e. grammatical) limits.

## Producing, Storing and Retrieving Information

A few words may be in order about the *data bases* ALP uses. A first data base consists of the Prolog program itself, made up of clauses embodying both facts and rules.

This data base is increased by running the **makelex** program, which involves expanding its macro-clauses. This process yields new lexical clauses, resulting from the generation of the morphological variants for regular lexical items such as adjectives, nouns and verbs. The irregular or invariant forms are entered directly as *lex* clauses. Let us look at examples of both:

a) directly entered as *lex* clauses:

*semper* (invariable):

```
lex(semper,adv,[lex:semper,pos:adv,type:clausal, sem:time]).
```

*simus* (irregular)

```
lex(simus,v,[pos:v,class:v_esse,type:finite,lex:esse,
            voice:act,txt:simus ,tense:present,kind:std,mood:subjunctive,
            number:pl,person:1]).
```

b) generated on the basis of a macro-clause:

```
lex(rogabis, v, [pos:v, class:tr_cod, type:finite, lex:rogare, voice:act, txt:rogabis, tense:future, kind:std, mood:indicative, number:sing, person:2]).
lex(rogabit, v, [pos:v, class:tr_cod, type:finite, lex:rogare, voice:act, txt:rogabit, tense:future, kind:std, mood:indicative, number:sing, person:3]).
lex(rogabit, v, [pos:v, class:tr_cod, type:finite, lex:rogare, voice:act, txt:rogabit, tense:future, kind:std, mood:indicative, number:pl, person:2]).
```

If we go to the macro-clause itself, we see that it uses the root provided by a *verb* clause (in this case for the verb *rogo*) and the list of endings suitable for that verb, to generate the morphological variants. Each variant is then turned into the first argument of a *lex* clause, the remaining arguments being the Part of Speech and a list of features (tense, mood, person, etc.) to be associated with that particular variant. The resulting new bunch of *lex* clauses (such as the three above) are then asserted by the macro-clause, i.e. added to the Prolog data base.

The verb clause for *rogo* (entered as such as part of the Prolog program) reads:

```
verb([v(rogare,1,rog,rogau,rogat)],tr_cod,std).
% the v functor encompasses infinitive, conjugation and the three roots. We then have the verb class, and
% the indication that the verb behaves 'standardly' with respect to the production of morphological variants
```

The macro-clause involved is much too long for it to be given in full in this introduction. Suffice it to say that it needs access to the relevant roots and endings, and performs atom-concatenation to produce the morphological variants. The atoms it concatenates (i.e. chains together in the order specified) are simply the relevant roots and endings.

The process results in the production of 213 *lex* clauses for the morphological variants of *rogo*, among which the three given above. The full list is to be found at the end of this document, just before the Appendices

As for the predicate-argument structure associated with the verb, it is the object of a specific clause for each verb. Such are the *lexarg* clauses, whose first argument is the arg-bearing element (in this case the verb *rogare*) and the second the *arglist feature*, whose value is a list of *word senses* accompanied by the arg structure they require.

% ROGARE

% Examples of the word senses accounted for in ALP

% Eo auxilium rogatum.

Ask for

% Rogebant quae fortuna exercitus esset.

Ask

```
lexarg(rogare,
  arglist:[ws(rogo_ask_for,tr_cod,clause:[],mwuw:0,
    args:[subject:[type:np,oblig:yes,constraints:[sem:[hum]]],
    object:[type:np,oblig:yes,constraints:[case:acc]]]),
    ws(rogo_ask,tr_cod,clause:[],mwuw:0,
    args:[subject:[type:np,oblig:yes,constraints:[sem:[hum]]],
    object:[type:pred,oblig:yes,
    constraints:[type:finite,mood:subjunctive, checkint:yes]])]).
```

In the example for *rogare*, we distinguish between two wordsenses, to capture the distinction between *rogo* meaning *ask* and *rogo* meaning *ask for*. *Rogo* meaning *ask for* has an np as object, whereas *rogo* meaning *ask* governs a clause, with its own constraints: it must be finite, its mood must be subjunctive, and it must be interrogative. The other requirements we hope do not need further explanation.

We now move on to discuss the second type of data base used by ALP.

This data base has a limited life-span. It is specific to each sentence being parsed, and is erased as soon as the sentence has been parsed. It houses all the productions that the production rules embodying the parser have generated all through the parsing process of that sentence, from working out the positions of the items within the string, down to the structures corresponding to a full parse of the input string.

It should be clear that while processing a sentence, no information yielded by the production rules is ever erased. The process is strictly incremental, producing bits of structure that will or will not contribute to the final parse or parses. That will be decided by the higher levels materialized by higher passes, the structures retained as valid parses having to span the whole string.

In such a system the linguist *describes* rather than sets about specifying the way the information he gives in the grammar and lexicon should be used (in what order, under what conditions, etc.). As soon as the coverage is to be more than strictly minimal, it makes a hell of a difference for the linguist's job if he hasn't to turn into a programmer each time he wants to add new lexical items, and, above all, new constructions.

The predicates for adding information to, and removing information from, that second type of data base, are specific to it. Instead of the *assert/retract* pair (used for the permanent db), we have the *recorda/erase* pair. No confusion is possible.

*Recorda* works with as many storage areas (called *Boxes* in ALP) as one wishes, and can store any Prolog term, i.e. anything ALP is ever likely to produce, from tiny lexical bits up to whole parses.

We use *recorda* both to store information and to retrieve recorded information.

Information gets stored in this second type of data base if it is not already there. The situation in

which the parser can no longer record new information signals the end of the parsing process. We use two predicates, *map* and *mapped*, the first to store, the second to retrieve information. They are defined as follows :

```
map(Box,FS) :- not(recorded(Box,FS,_)),
               recorda(Box,FS,_).
               % the not recorded condition is essential for keeping track of a 'no new solution' situation
               % which enables the various parser runs to come to an end
               % in most cases FS is a list of features

mapped(Box,X) :- recorded(Box,X,_).
```

Note that we do not bother about the third argument of either *recorda* or *recorded*. Remember that using the anonymous variable (`_`) is the standard way of indicating that one is not interested in the information stored there. As a matter of fact, we could have used the two-arg versions of *recorda* and *recorded*, also part of SWI-Prolog, which simply leave out the information we are not interested in.

## Mapping

To illustrate this process, we can look at the treatment of simple np groups made up of a noun and an adjective phrase as in *agricola doctior Petro*. We take up the analysis at a point where the adjective phrase has already been built and needs to be attached to the noun to build the resulting np.

We give the commented Prolog code, adding some more comments in an attempt to persuade the reader to stay with us a few pages more...

```
% adj phrase following the noun
```

```
[finite,np2a] -> % category and name of the rule
```

```
[mapped(noun,[from:A, to:B]FSnoun)], % we have a noun in the word list corresponding to the input string  
% it extends from position A to position B  
% its feature bundle has been read off the lexicon  
% in the case of agricola (taking it as a nominative), it would be  
% [pos:noun, txt:agricola, lex:agricola, case:nom, gender:masc, class:common, number:sing, sem:[hum]]
```

```
mapped(adjp,FSadj),  
% we have an adjective phrase (here covering doctior Petro) with its own feature bundle, sth along the  
% lines of
```

```
% [cat:adjp,pathlist:Sorted,distance:Distance,hp:[p(A,B)],  
% case:Case,number:N, gender:G,lex:Lex,type:Type,w:Weight,  
% c_str:[Lex,comp_cplt:FSnp]]
```

```
% with the variables duly instantiated
```

```
constraint([number:Nb,gender:Gender,case:Case,class:Class,sem:Sem,lex:LexNoun],FSnoun),
```

```
% we select from the feature bundle associated with the noun  
% the values for number, gender, case, etc.
```

```
constraint([number:Nb,gender:Gender,case:Case,lex:LexAdj,type:Type,w:W],FSadj),
```

```
% we select values from the feature bundle associated with the adjective phrase,  
% leaving unification to check that the agreement triplet Number, Gender, Case holds
```

```
Type \= int, % interrogative adjectives dealt with separately - they need heavy weight
```

```
constraint([pathlist:Padj],FSadj),  
% we retrieve the pathlist of the adjective phrase
```

```
append([p(A,B)],Padj,Pnp),  
% we append i.e. concatenate the path for the noun and the path for the adjective phrase
```

```
extremity(Padj,Ext), % we select the endpoint of the path covered by the adjective
```

```
Ext > B, % here the adj phrase follows the noun, B being the endpoint of the noun
```

```
distance([p(A,B)],Padj,Distance), % the distance between the noun and the path of the adjective  
% determines the straining factor as well as helping to decide  
% whether noun and adj DO belong together  
% the straining factor will contribute negatively to the weight assigned  
% to the parse
```

```
ifthen(LexAdj=is, Distance=0), % is/ea/id adjacent - this requirement is probably too strong
```

```
msort(Pnp, Sorted), % merge sort  
\+dup(Sorted), % no duplicates – recall that \+ is the negation operator in Prolog
```

```
% we standardly apply this couple of procedures to paths  
% first, we sort them ; second, we check that they do not contain duplicates
```

```
Distance < 4, % 3 is thus the maximum distance  
% between adj and noun  
% a Prolog call that acts as a barrier – if it fails, the whole thing fails
```

```
% we still have to exclude the occurrence, within the gap, of nouns to which the adjective could be
% attached with priority, because they agree in the well-known agreement triplet
% we use relaxedadjacentN_cgn
% (where N=1,N=2,N=3, and cgn means that case gender and number are checked for agreement)
```

```
ifthen(Distance=3, relaxedadjacent3_cgn([p(A,B)],Padj,Case,Gender,Nb)),
    % three in between, neither of them a noun with relevant triplet
ifthen(Distance=2, relaxedadjacent2_cgn([p(A,B)],Padj,Case,Gender,Nb)),
    % two in between, neither of them a noun with relevant triplet
ifthen(Distance=1, relaxedadjacent1_cgn([p(A,B)],Padj,Case,Gender,Nb)),
    % one in between, not a noun with same [gender,number,case] triplet
```

```
% Weight is W+1,
% we increase the weight of the adjective phrase (as computed when the phrase was parsed)
% with the weight assigned to a single noun, i.e. 1
% myplus is the same as plus, but does not fail if it meets with a variable instead of a number
myplus(W,1,Weight), % means W+1=Weight, a formulation that would lead to disaster in Prolog,
    % since the equal sign (=) is used for unification, not addition !!!
    % standard Prolog requires Weight is W+1
```

```
% we can now build the resulting NP
% note that the head of the NP is the N,
% which also yields the index reference used for binding traces (as in relative clauses)
```

```
map(np,[pathlist:Sorted,hp:[p(A,B)],index:i(p(A,B)),distance:[Distance], % distance is recorded as
    % straining factor
    cat:np,class:Class,sem:Sem,
    number:Nb,person:3,gender:Gender,type:core,lex:LexNoun,lextype:full,
    case:Case,w:Weight,
    c_str:[head:FSnoun,adjp:FSadj]]).
```

the *c\_str* is the constituent as it appears in the parse tree : (we use the parse produced by ALP for the sentence : [0/agricola,1/doctior,2/petro,3/misit,4/reginae,5/epistulam,endpos(6)], selecting the bit assigned to the subject (*agricola doctior Petro*) :

```
subject:[pathlist:[p(0,1),p(1,2),p(2,3)],hp:[p(0,1)],index:i(p(0,1)),distance:[0],
    cat:np,class:common,sem:[hum],
    number:sing,person:3,gender:masc,
    type:core,lex:agricola,lextype:full,case:nom,w:3,
```

```
c_str:[head:[pos:noun,txt:agricola,lex:agricola,case:nom,gender:masc,class:common,number:sing,sem:
[hum]],
```

```
    adjp:[cat:adjp,pathlist:[p(1,2),p(2,3)],distance:[0],hp:[p(1,2)],
        case:nom,number:sing,gender:masc,
        lex:doctus,type:std,w:2,
```

```
c_str:[doctus,
    comp_cplt:[pathlist:[p(2,3)],hp:[p(2,3)],index:i(p(2,3)),distance:[0],
        cat:np,sem[hum],class:proper,
        lex:petrus,lextype:full,number:sing,person:3,gender:masc,
        type:core,case:abl,w:1]]]]
```

which pretty-prints as:

```
subject
  index:i(p(0,1))
  cat:np
  sem:[hum]
  number:sing
  person:3
  gender:masc
  lex:agricola
  case:nom

          case:abl
```

## Matching

Since we have been looking at *arglists*, we'll now say a few words about the process by which the argument requirements are satisfied, i.e. matched with structures to be found in the string to be parsed. We have already pointed out that the args do not have to be found in the canonical order in which they appear in the *arglist*. It also stands to reason that the args marked as optional need not be instantiated, but if they are, they contribute to the weight assigned to the predicate-arg nexus.

Consider the matching of the *subject* arg. We have already seen that the subject could be projected from the verb group, which is the standard case when the subject is first or second person, but a third person subject may also be textually retrievable.

Voice will affect the arglist. In the passive voice, the object arg will be assigned the subject function, and the subject arg will be demoted to a prepositional phrase status (ab+ablative) or will be assigned the ablative case, and will in all cases be optional. Such transformations to the arglist must be accomplished as soon as we have ascertained the predicate's voice, which should be early enough in the parsing process (but remember a very important property of the production system: rules fire automatically when the material they need is ready, i.e. has been made available by lexical look-up or the previous firing of grammatical rules and their production of the required structures. It is NOT the linguist's task to worry about sequence in the application of rules. Considering the very highly recursive nature of grammar, this is a key property of production systems).

We'll now look at the code for updating the args to be matched in the case of a passive voice being found in the arg-bearer, i.e. the predicate, in a non-finite clause (*puto reginam ab ancilla marci amari*).

```
mapped(vg,FSverb),
constraint([type:nonfinite,mood:Mood,voice:Voice,tense:Tense,      % nonfinite verb form (in our case: amari)
           pathlist:PathlistVerb,lex:Clex, w:WVerb],FSverb),
```

```
lexarg(Clex,arglist:ArgList), % connection with the args via lexarg
                                % the args are those for amo:
lexarg(amare,
arglist:[
ws(amo_love,tr_cod,clause:[],mwuw:0,
args:[subject:[type:np,oblig:yes,constraints:[sem:[hum]]],
object:[type:np,oblig:no,constraints:[case:acc]]])).
```

```
pick(ws(Lex,Class,clause:Clause_Constraints,mwuw:MW,args:Args), ArgList,_),
    % picking a word sense to see if it is appropriate ...
    % remember that in general there will be more than one
    % ws (i.e. word sense) for a given arg-bearer
```

```
ifthenelse(Voice=pass,           % outer THEN           % PASSIVE, as here amari
```

```
% selecting the object to remove it from the arglist and turn it into a subject
```

```
(pick(object:ObjectSpecs,Args,Args1), % note that there must be an object if a passive was produced !!
pick(oblig:Oblig, ObjectSpecs,OS1), % but perhaps it was not obligatory, as in the case of amare
pick(constraints:Oconstraints,OS1,OS2), % and we must also update the constraints
pick(case:Caseobj,Oconstraints,Oconstraints1),
                                % recall that the predicate pick selects an element and
                                % removes it from the list
                                % case is buried within the constraints associated with the arg
                                % we pick it out
```

[illegible]

```

append([constraints:NewOconstraints],OS2,NOS),
append([oblig:yes],NOS,NewObjectSpecs),      % there must be a subject if a passive is used !!!

% turning the subject into an optional (a+) abl pp arg
pick(subject:SubjectSpecs,Args1,Args2),
pick(constraints:Sconstraints,SubjectSpecs,SS1),

ifthenelse( Sconstraints=[],
            % no constraint on subj: both types of agent are OK      IF-CLAUSE

            ( NewArg=[type:pp,oblig:no,constraints:[prep:ab,sem:[hum]]] ;
              % THEN-CLAUSE note the OR operator (;)
              NewArg=[type:np,oblig:no,constraints:[case:abl,sem:[thing]]] ) ,

            % ELSE-CLAUSE:

            % ab+hum vs simple abl for non-hum

            ifthenelse( constraint([sem:[hum]],Sconstraints), % IF2-clause      case of amare
                      % there are constraints: we act accordingly
                      NewArg=[type:pp,oblig:no,constraints:[prep:ab,sem:[hum]]], % THEN2-clause
                      NewArg=[type:np,oblig:no,constraints:[case:abl]]), % ELSE2-clause

                      append([agent:NewArg],Args2,At),
                      append([subject:NewObjectSpecs],At,Argstomatch) ), % reconstructing the arglist

            Argstomatch=Args), % outer ELSE: ACTIVE : leave the args as they are in the arg specs

% the remainder of this bit of code concerns the matching of the new arglist
% and is not discussed here

```

## A Voice in the Middle...

Since we have been discussing voice, this might be the right place to point out that ALP works with a *middle* voice, by the side of the active and the passive.

Morphologically, we generate forms that look like passives, but concern third person singular of intransitive verbs, e.g. *insanitur*, *insaniatur*, *insaniebatur* and *insanietur* for *insanio*, for instance. This middle voice is much nearer to active than to passive. The passive touch is found in the generality and impersonality of the process, which can convey a sense of passivity and inevitability: *Ibatur in caedes*...

```

```

## Relative Clauses

We deal with relative clauses in a way that may prove somewhat surprising to a linguist not used to working with *indices* and *gaps*. Consider a relative clause from which the relative pronoun has been removed:

*(qui relinquit reginam / quem relinquit rex) → relinquit reginam / relinquit rex*

we can look at such structures as a *pred-arg nexus missing an argument*, subject in the first case, object in the second (this is not the only reading, it's the reading that we give these structures when we know that they are incomplete, that they miss something). The missing arg is of course the relative pronoun, but the relative pronoun on its own does not give sufficient information to guarantee that all the constraints on the missing arg are met. The relative pronoun must be put into relation with its antecedent, and then we can complete the checking of a number of constraints, for instance of a semantic nature. The relation between antecedent and pronoun, and thereby between the antecedent and the gap in the incomplete predication discussed above, is implemented by *index sharing*. The index is no more than a pointer and can be coded in Prolog by a one argument structure, *i(Index)*, where *Index* is a variable to be shared by all instances of an index pointing to the same thing. The variable *Index* would then be shared by the triplet *missing arg/relative pronoun/antecedent*. We can increase the readability of our parses if we use a pair of values instead of the *Index* variable. This pair of values can be assigned as index each time we posit a noun phrase head: the values will be the start and end positions of the NP head in the string. To give an undoubtedly welcome example, in the sentence

*rex qui relinquit reginam malus est*

*rex* will be assigned *i(0,1)* as an index, which will come to be shared by *qui* and the missing arg of the *relinquit*-arg nexus (where it is often known as a *trace* or a *gap*). If *relinquit* needs a human subject (it does!), the constraint will be placed on the gap, passed on to the relative and to its antecedent, where it will be found to be satisfied.

The assigned parse follows:

```

We will briefly go into the index assignment and index sharing procedure, a procedure considerably facilitated by Prolog unification.

First, whenever we build an np, we assign an index corresponding to the path of its head, as in (the simplest possible case of an np built out of a single noun):

```
[core,np1] --->
[mapped(noun,[from:A,to:B|FS]),
constraint([pos:noun,lex:Lex,class:common,sem:Sem,txt:Text,
            number:Nb,gender:G,case:C],FS),
map(np,[pathlist:[p(A,B)],hp:[p(A,B)],index:i(p(A,B)),distance:[0],
        cat:np,sem:Sem,class:common,lextype:full,
        number:Nb,person:3,gender:G, type:core,lex:Lex,txt:Text,
        case:C,w:1]])].
```

Second, we map relative clauses as consisting of a relative pronoun followed by a predication which misses an argument, and we relate the missing argument to the relative (in the code given below, the relative pronoun is subject, as in *uir qui epistulas ad Marcum misit*)

```
% Recall that the function of the np is independent from its function in the relative clause:
% "liber quem rex legit ..." : liber is subject in the main clause and quem is object in the relative
% The index is shared; it reports the positions spanned by the np.
% A relative clause is an S displaying a [gap:Gap] feature corresponding to the antecedent:
% same category (np, pp) and shared index
% The gap site can specify any type of constraints on the constituent structure of the antecedent NP;
% this power is necessary to deal with mwus where the deletion site
% can point to an NP that must be lexically described,
% not just in terms of features such as number and broad semantic category

%% with a relative pronoun filling an np slot
% "(vir) qui epistulas ad Marcum misit" ; "(librum) quem ancilla legit"

% subject

[finite,rel_clause_1] --->
[mapped(relative,[from:X,to:Y|FS1]),                                     % a relative pronoun

constraint([number:Nb, case:Case,gender:Gender, function:Functions],FS1),

mapped(pred,FS2),                                                     % a clause

constraint([type:finite,                                             % relative clauses are finite
            mood:Mood, tense:Tense,pathlist:Pathlist,distance:Distance,w:Weight],FS2),

msort(Pathlist,Sorted),

                                                                    % is an instantiated (bound) variable when the call to
                                                                    % nonvar is made
                                                                    % without such a test the danger is that the following test
                                                                    % be no test at all, but should merely result in unification
                                                                    % of the GAPARG variable with whatever comes its way

GAPARG=[gap:[type:np,                                                % GAP specifies type
            index:Index,      % opens a place for the Index of the antecedent to fill
            function:subject, % function must be compatible with relative pronoun
            subject:[e:Index], % info for the parse tree - e (empty, trace) followed by the Index
            constraints:Constraints % we put the constraints to be checked on the antecedent in this box
            ],

member(subject,Functions),      % remember that the acc rel pronouns must bear the 'subject' function as well as the
                                                                    % object one

append([p(X,Y)],Pathlist,Pnew), % appending the relative pronoun to the path
```

```

map(relative_clause,[pathlist:Pnew,
                    distance:Distance,
                    gap:GAPARG,      % gap info carried by the clause
                    index:Index,
                    number:Nb,
                    gender:Gender,
                    case:Case,
                    type:finite,
                    mood:Mood,
                    tense:Tense,
                    constraints:Constraints,
                    w:Weight,
                    c_str:C_str]) ].

% similar treatment for the other functions (object, etc.)

We should now look at the building of a gapped predication. Whenever we are trying to match an argument with a phrase in the string to be parsed,
we allow that argument to be matched with nothing at all in the string, with the proviso that it create a GAP, a structure which houses the
requirements that the arg would have filled if it had been found in the string. Again, we look at the subject in finite clauses:

% in finite clauses
% the subject is the one of the potentially main clause, i.e. the 'up' one
% rex qui // [subject-gap] amat reginam

match(subject:Specs,
      subject:[index:Indexup],
      [number:Nsubj,gender:Gendersubj,person:Psubj,index:Indexup],
      [],
      [0],
      finite,
      gap:[gap:[type:Type,
                index:Indexup,
                function:subject,
                subject:[e:Indexup],
                constraints:GapConstraints]],
      w:1,
      Int) :-

constraint([type:Type,constraints:Constraints],Specs),
Type \= dummy,
append([number:Nsubj,gender:Gendersubj,person:Psubj,case:nom,index:Indexup],Constraints,GapConstraints).

% remember that a gapped constituent simply puts its constraints in the Gap feature,
% to be satisfied when the pred is connected to the antecedent

```

It remains for us to look at how the junction between the relative clause and its antecedent is accomplished. The index of the np is projected into the relative clause; the constraints housed in the relative clause should be met, with the exception of case, which need not be shared between antecedent and relative pronoun (and thereby the GAP structure of the relative).

```

% NP WITH RELATIVE CLAUSE
[finite,np6] --->

[
    mapped(np,FS1),
    constraint([pathlist:PL1,hp:HL1,distance:[Distnp1]],FS1),
    constraint([cat:np,index:Index,number:Nb,gender:G,
               sem:SemNP,lex:Lex, case:Case],FS1),

    mapped(relative_clause,FS2),
    constraint([number:Nb,gender:G,pathlist:PL2,distance:[Distrel], constraints:Constraints,w:W],FS2),

    constraint([index:Index],FS2), % index sharing with the NP - essential to link relative and antecedent

    cleanc(Constraints,CC),
    % the Constraints should not include Case (to be removed - other constraints to be kept)
    ifthen(CC\=[],constraint(CC,FS1)),
    % apply the constraints, e.g. semantic constraints passed on to the antecedent noun

myplus(W,1,Weight),

map(np,[pathlist:Sorted, hp:HL1,distance:[Distance],
      cat:np,type:full,class:common,lextype:full,
      index:Index,number:Nb,gender:G,sem:SemNP,person:3,case:Case,
      lex:Lex,w:Weight,c_str:[head:Lex,rel_clause:FS2]])
].

```

Needless to say, perhaps, the phenomenon described as *interlacing* in relative clauses (see Pinkster, Vol. II, 18.12) is well beyond the power of ALP. Consider the well-known example from Livy :

*nec Alpes aliae sunt, quas dum superant comparari nova possint praesidia.* (Liv. 21.41.15)

and its translation in one of our Latin-derived languages such as French :

*et il n'existe pas d'autres Alpes telles que nous pourrions préparer des renforts dans le temps que les ennemis prendraient pour les franchir.*

French sounds long-winded perhaps (or only my translation does<sup>7</sup>), but is kinder on the reader : one thing at a time... a literal translation shows the distance between the two languages (literal transl. Uri, standard tr. Gaucher) :

*nec aliae Alpes sunt -----ni d'autres Alpes ne sont*  
*quas dum superant -----lesquelles pendant qu'ils traversent*  
*nova praesidia -----de nouvelles troupes*  
*possint comparari -----puissent être préparées*

*(pas d'autres Alpes qui le retardent et nous permettent de lever de nouvelles forces)*

*(nor are there other Alps to obstruct his advance while we make ready new defences)*

To account for such interlacing we would have to allow the gap left by the relative pronoun to fill in an arg slot (object of *superant*) in a subordinate clause that is not even an argument in the relative clause itself (*dum superant* is a satellite clause with respect to *comparari nova possint praesidia*). Although technically feasible such a treatment would open the door to an untameable crowd of spurious readings.

---

7 plus d'Alpes nouvelles, dont le passage arrête Hannibal, et nous donne le temps d'armer contre lui de nouveaux bras.  
(trad. Collection Panckoucke 1909)

## Prioritizing Subject-object Order in Accusative-cum-infinitive Clauses

In nonfinite dependent clauses, namely in accusative-cum-infinitive clauses, we might encounter accusative pairs, and even accusative triplets in the case of double-accusative verbs of the *doceo*-type:

*Putabas reginam regem amare.*

*Putabas ancillam pueros grammaticam docere.*

The accusatives can play the parts of subject, object, and even indirect object in the argument structure of *doceo*-type verbs.

Suppose we wish to prioritize the standard order of args in the clause, with the subject preceding the object(s), without rejecting readings in which the subject follows either or both of the objects:

*Putabas reginam regem amare:*

Preferred reading: *reginam* subject, *regem* object:

*You thought the queen loved the king.*

Deprioritized but possible reading: *regem* subject, *reginam* object:

*You thought the king loved the queen.*

*Putabas ancillam pueros grammaticam docere.*

Preferred reading: *ancillam* subject, *pueros* indirect object, *grammaticam* object:

*You thought the servant was teaching the kids grammar.*

Deprioritized but possible reading:

*ancillam* indirect object, *pueros* subject, *grammaticam* object:

*You thought the kids were teaching the servant grammar.*

Rejected readings (on semantic grounds: both the subject and indirect object must bear the feature +HUM):

*grammaticam* subject, *pueros* indirect object, *ancillam* direct object:

\* *You thought the grammar was teaching the kids the servant.*

*grammaticam* subject, *pueros* object, *ancillam* indirect object:

\* *You thought the grammar was teaching the servant the kids.*

The parser should come up, and does come up, with the following ranking of the two retained parses:  
[0/putabas,1/ancillam,2/pueros,3/grammaticam,4/docuisse,endpos(5)]

It should be borne in mind that the accusative-cum-infinitive construction might be found inside a relative clause: in such cases, a correct parsing procedure must identify the nature of the trace (gap) in the relative clause, and ensure the proper indexing of it by index-sharing between antecedent and trace.

Consider:

*Amas grammaticam quam putabas ancillam pueros docuisse.*

In the accusative-cum-infinitive clause [*ancillam pueros docuisse*] inside the relative clause [*quam putabas ancillam pueros docuisse*] we need to posit a gap (symbolized in the parse tree with an *e* for *empty*) for the object of *docuisse* and associate that gap, by co-indexing, with the antecedent of the relative, i.e. *grammaticam*.

We do this by assigning an index referring to the position occupied by the antecedent in the word list derived from the input string:

[0/amas,1/**grammaticam**,2/quam,3/putabas,4/ancillam,5/pueros,6/docuisse,endpos(7)]

The antecedent *grammaticam* spans from 1 to 2:  $p(1,2)$ .

The index for the missing arg within the infinitive clause (the object arg) must therefore bear the index  $p(1,2)$ , as it does in the parses returned by the parser. Once again, the parse tree where the order subject-object is maintained is prioritized

It might be worthwhile taking a quick look at the way the Prolog program embodying the parser deals with the subject-object order prioritization in the accusative-cum-infinitive construction:

```
% prioritize normal subject-object order

ifthenelse(constraint([subject:[hp:Pathsubj]],ST),
            % we have a non-gapped subject, we record its head path
            true,                                     % and abstain from doing anything else
            Pathsubj=[p(0,0)]),
            % otherwise the subject is higher up and therefore necessarily precedes

ifthenelse(constraint([object:[hp:Pathobj]],ST),      % IF-CLAUSE we have an object
            ifthenelse(precedes(Pathsubj,Pathobj), NW is Weight+1, NW=Weight),
                    % THEN-CLAUSE
            NW=Weight),                               % ELSE-CLAUSE

ifthenelse(constraint([i_object:[hp:Pathiobj]],ST),   % we have an indirect object
            ifthenelse(precedes(Pathsubj,Pathiobj), NW1 is NW+1, NW1=NW),
            NW1=NW),
```

To understand this bit of code, one needs to know that the **hp** (HeadPathList) feature above records the positions spanned by the head of the noun phrase filling in the arg position of the parent feature: subject, object, or indirect object.

Remember that if the subject is gapped, it does not have a **hp** feature since it does not occur in the clause: there is no subject present in [*epistulam misisse Marco*] as object of *putas* in [*putas epistulam misisse Marco*], itself included in the relative clause [*quem putas epistulam misisse Marco*] appended to the antecedent *rex* in [*Rex quem putas epistulam misisse Marco*] which functions as subject of the whole S(entence): [*Rex quem putas epistulam misisse Marco*] *amat ancillam reginae*.

In the case of such a gapped subject we assign it a dummy headpathlist, namely [p(0,0)], which is sure to precede the pathlist of any arg found in the clause.

Otherwise we record the value of the *hp* feature and we can then compare it with the values of the headpathlists for the object and indirect object, if available, and proceed to the prioritizing by increasing the current Weight assigned to the parse tree being built.

We have seen that the *precedes* predicate is trivially simple to code; we know that the *constraint* predicate implements feature unification. It is used here to retrieve values for features possibly instantiated in the feature bundle *ST*, which records the structure and properties of the arguments filling in the arg slots opened up by the predicate.

## Binding se

The issue is well-known. The *se* family (*se*, *sui*, *sibi*) offers the possibility of multiple binding: a local binding in the clause of which *se* is a constituent, and outer bindings in higher clauses, i.e. clauses having the *se*-bearing clause as an argument or as the argument of one of their arguments, and so on climbing up the parse tree.

We wish to insist on one point: reference belongs to discourse. The only thing grammar can do is to suggest candidates and provide limits to the search for referents.

In ALP we bind *se* locally, unless there is a governing clause above the one in which *se* occurs, in which case we bind 'one up', i.e. to the subject of the governing clause. In *laudant se*, we bind *se* to the context-retrievable subject of *laudant*, to which we assign *i(0,0)* as index; in *laudant se reges*, we bind *se* to *reges*; in *me sibi epistulas dedisse dicit*, we bind *sibi* to *i(0,0)* again:

*Laudant se :*

where the emphasis due to *ipsam* prevented the binding of *se* with masculine *rex*.

The *se*-binding process also applies to subordinate clauses that function as arguments, for instance *ut*-clauses. Our example is once again that given by H.Pinkster in the *Oxford Latin Syntax* :

*Nam illa mulier lapidem silicem subigere ut se amet potest* (Plautus, Poen. 290)

How do we proceed ?

Remember that in ALP each *NP* is associated with an *index* which records the *string position* of its *head*.

Whenever we encounter (while turning the input string into a word list) a member of the *se* family, we flag the sentence so that it will be the object of the *se*-binding process :

```
positions([Head|Tail],Pos,Listofwords) :-  
    ifthen((Head=se;Head=sibi;Head=sui), recorda(flags,active(se)) ),
```

Encountering a member of the *se* family leads to the mapping of a *np* ; two cases are taken care of, *se* alone, or *se* emphasized with *ipse* :

```
% 3rd person reflexive pronouns are given a variable as index -  
% the index will be instantiated with a value inside or outside the clause  
  
% both non-emphatic and emphatic (se / se ipsum)  
  
% emphatic  
  
[core,np22] --->  
[mapped(prpers,[from:A,to:B|FS1]),  
constraint([case:Case,sem:Sem, lex:pp3refl],FS1),  
mapped(adjp,FSadj),  
constraint([pathlist:[p(B,X)],number:Number,gender:Gender,case:Case,lex:ipse],FSadj),  
map(np,[pathlist:[p(A,B),p(B,X)],hp:[p(A,B)],index:_,distance:[0],  
cat:np,sem:Sem,class:proper,lex:pp3refl,emphasis:yes,  
number:Number,person:3,gender:Gender,type:core,case:Case,w:2,constituent_structure:pp3refl])].  
% the lex value catches the reflexive pronouns of the third person  
% 'ipse' follows : 'se ipsum' not * 'ipsum se'  
% the index will be instantiated when the parse is ready for output  
% here the value is left unassigned  
% binary emphasis feature  
  
% non emphatic  
  
[core,np23] --->  
[mapped(prpers,[from:A,to:B|FS1]),  
constraint([case:Case,sem:Sem, lex:pp3refl],FS1),  
map(np,[pathlist:[p(A,B)],hp:[p(A,B)],index:_,distance:[0],  
cat:np,sem:Sem,class:proper,lex:pp3refl,emphasis:no,  
number:Number,person:3,gender:Gender,type:core,case:Case,w:1,constituent_structure:pp3refl])].
```

We work on the parse when it's ready for output, exploring the tree structure via the value of the *constituent\_structure* feature and binding the indices for *se*, left uninstantiated up to that point.

```
ifthen( mapped(flags,active(se)), ifthen(bind_se(Pred),true)),  
    % we have a member of the se family  
    % we apply binding without allowing failure  
    % we are only interested in the side-effects of the binding procedure
```

We allow the binding to work its way down the constituent structure. Here we explore only the top level and the next level down.

```
% TOP LEVEL
```

```
bind_se(ParseTot) :-
```

```
constraint([constituent_structure:[_|Parse]],ParseTot), % we get at the Parse stricto sensu
```

We use condition-action *ifthen* clauses with the action reduced to 'true', i.e. no action to be taken and no failure if the condition is not satisfied ; we must ensure that the *se*-binding process never leads to failure. We use the *ifthen* with no failure all through.

```
ifthen(
    constraint([subject:[cat:np,sem:[hum],gender:GUP,number:NUP,index:IndexUP]],Parse), true),
% retrieving index, gender and number of the subject at the highest level
```

we then retrieve the args that can be subjected to *se*-binding : object, *i\_object* and prepositional complement ; the 'true' action ensures that no failure is reported if they are not part of the clause

```
ifthen( constraint([object:OBJ1],Parse), true),
ifthen( constraint([i_object:I_OBJ1],Parse), true),
ifthen( constraint([prep_cplt:PREPCPLT1],Parse), true),
```

We have them if they are there to be had. If they are, then they have been instantiated and we can impose the info retrieved from the subject : index, gender, number. The condition being, of course, that they are third person reflexive pronouns :

```
ifthen( (nonvar(I_OBJ1),constraint([lex:pp3refl],I_OBJ1)),
        constraint([gender:GUP,number:NUP,index:IndexUP],I_OBJ1)),
ifthen( (nonvar(OBJ1),constraint([lex:pp3refl],OBJ1)),
        constraint([gender:GUP,number:NUP,index:IndexUP],OBJ1)),
ifthen( nonvar(PREPCPLT1),
        constraint([index:IndexUP,lex:pp3refl,constituent_structure:[head:
                                                                [gender:GUP,number:NUP,index:IndexUP]]],PREPCPLT1)),
```

If the object is a clause (*cat:pred* condition), we retrieve its constituent structure, and we are ready to carry the *se*-binding process one level down :

```
ifthen( (nonvar(OBJ1),constraint([cat:pred],OBJ1)),
        constraint([constituent_structure:CSTROBJ1],OBJ1)),
```

% ONE DOWN

```
ifthen( nonvar(CSTROBJ1),(constraint([subject:SUBJ2],CSTROBJ1);true) ),
ifthen( nonvar(CSTROBJ1),(constraint([object:OBJ2],CSTROBJ1);true) ),
ifthen( nonvar(CSTROBJ1),(constraint([i_object:I_OBJ2],CSTROBJ1);true) ),
ifthen( nonvar(CSTROBJ1),(constraint([prep_cplt:PREPCPLT2],CSTROBJ1); true) ),
```

We bind the reflexive pronoun in subject position with values inherited from the next level up. If the subject is not a reflexive pronoun, we retrieve the number, gender and index of this new subject to have them ready to bind one level further down (NMIDDLE, etc.). We apply a similar treatment to the other args at the same level.

Note that if we have a disjunction in the action associated with an *ifthen* clause, and the first action can be carried out successfully, the second one will not be attempted. So, in the case for instance of the object being a reflexive pronoun, the binding will be with the subject of the higher clause ; but if such binding fails, the second action is carried out, and the values of the reflexive pronoun will be those retrieved at the level being considered, not the level above. So, in the case of a plain *se*, the binding of *se* in *rex putat reginam se amare* will be with *rex* ; but if we have got *se ipsam*, as in *rex putat reginam se ipsam amare*, the constraint projecting the values of *rex* on the reflexive pronoun *se ipsam* will fail (because of the gender associated with *ipsam*) and the binding will be

with the subject at the level of the object clause, namely *reginam*.

```
ifthen( (nonvar(SUBJ2), constraint([lex:pp3refl],SUBJ2)),
        constraint([index:IndexUP,number:NUP,gender:GUP],SUBJ2)),

ifthen( (nonvar(SUBJ2), constraint([cat:np,lex:Lex2,sem:[hum]],SUBJ2), Lex2 \= pp3refl),
        constraint([number:NMIDDLE,gender:GMIDDLE,index:IndexMIDDLE],SUBJ2)),

ifthen( (nonvar(OBJ2),constraint([lex:pp3refl],OBJ2)),
        ( constraint([gender:GUP,number:NUP,index:IndexUP],OBJ2) ;
          constraint([number:NMIDDLE,gender:GMIDDLE,index:IndexMIDDLE],OBJ2)
        )),

ifthen( (nonvar(I_OBJ2),constraint([lex:pp3refl],I_OBJ2)),
        ( constraint([gender:GUP,number:NUP,index:IndexUP],I_OBJ2) ;
          constraint([number:NMIDDLE,gender:GMIDDLE,index:IndexMIDDLE],I_OBJ2)
        )),

ifthen( nonvar(PREPCPLT2),(
        constraint([index:IndexUP,lex:pp3refl,constituent_structure:[head :
                                                                    [gender:GUP,number:NUP,index:IndexUP]]],PREPCPLT2) ;

        constraint([index:IndexMIDDLE,lex:pp3refl,constituent_structure:[head:
                                                                    [number:NMIDDLE,gender:GMIDDLE,index:IndexMIDDLE]]],PREPCPLT2)

        ),

),

% prep_cplt has a more complex buildup, we have to enter into the Head belonging to the C_str (Constituent Structure)
```

and then we get ready to move down a level, if there is one :

```
ifthen( (nonvar(OBJ2),constraint([cat:pred],OBJ2)),

```

and so on.

We wish to stress once again that parses should not be rejected on the basis of the candidates they put forward for reference. We need other tools to tackle the issue, which is only partly a matter for linguistics to handle, and certainly not one to be exclusively assigned to the syntactic component that is the core business of parsers.

## Weighting

We wish to stress that a weighting process is absolutely necessary for parsers. The parser is first and foremost a tool that yields structural descriptions of strings on the basis of what the linguist has specified as grammatical. If we do not build a weighting procedure on top, we will be presented with multiple parses of strings, all of them grammatical with respect to our grammar, although some of them may look very far-fetched, and, to put it bluntly, totally unacceptable as plausible readings of the string submitted to parsing. Consider the following example : *Amo magistros cupidos legendae historiae*, *I like teachers who are eager to read history (books)*.

The parse which gets the highest ranking in ALP is the natural one, in fact the only one that comes to mind when we read the Latin sentence (and the only one we expect the learner to work out): the sentence is made up of a predicate, *amo*, with first-person subject immediately derivable from the verb form; the predicate is transitive *amo*, which in the sentence has as object the noun phrase *magistros cupidos legendae historiae*, which is made up of a head, *magistros*, in the accusative as it should be, and an adjective phrase attached to it, namely *cupidos legendae historiae*, whose head, *cupidos*, is in its turn in the right case, gender and number. *Cupidus* is an argument-bearing adjective, its argument being a genitive phrase, noun phrase or gerund(ive) clause, as is the case here, the gerundive clause being *legendae historiae*, made up of a predicate, the gerundive *legendae*, and its argument, a noun phrase in the genitive case, *historiae*, *lego* being transitive just like the *amo* of two minutes ago. We have reached the end of the gerundive clause, the end of the argument of the adjective, the end of the noun phrase of which the adjective phrase is a part, the end of the argument of the main verb, the end of the sentence, the predicate having the two arguments it needs, a subject hidden in the verb form, and an object covering all the words except the predicate itself. Nothing could be simpler, there is no way of getting it wrong, and ALP certainly does not.

End of story? Well, there is Livy with *Pacis petendae oratores ad consulem miserunt* and Tacitus with *Germanicus Aegyptum proficiscitur cognoscendae antiquitatis*. And if we wish to account for the usage of our two historians, we need to make room for an adjunct of purpose built around a gerundive clause. And we run the risk of parsing our very simple sentence as meaning something along the lines of *I love greedy teachers in order to read history*.

In fact, there is no way of preventing the 'wrong' parse to come out, in so far as it is not a wrong parse at all – it is correct with respect to a grammar that is itself correct. What we can do to avoid the parse coming up to the surface is to deprioritize it, rank it down, or, what amounts to the same, prioritize what we regard as the natural parse, the one we have just shown to be the top choice of ALP.

The weighting procedure in ALP is based on two principles:

- 1) prefer tight links (such as that between a predicate and its arguments) over loose ones (an adjunct at clause level)
- 2) assign penalties to distortions of the underlying word order (where the subject precedes the object) and, first and foremost, to strains due to the distance separating elements which are naturally found together, such as an adjective or genitive np and the noun functioning as head of the resulting noun phrase.

The above strategies need to be put to work with a certain amount of care, so that they should cooperate rather than compete. We have also seen that we need the path algorithms studied above to put the second of them into practice.

We can't be certain, however, that the best parses will always get the best score. I'll give a single example. Because of Ovid's marvellous *elige cui dicas : tu mihi sola places*, ALP has long been too generous in assigning np status to relative clauses that have no antecedent ; to do so it builds nps with a dummy np-head to which the relative clause gets attached. A reasonable requirement would be that case be shared between this dummy np and the relative pronoun opening the antecedent-less relative :

*qui amat rex amat reginam* (nominative : subject – *qui amat rex* is subject of *amat reginam* in the same way as *qui* is subject of *amat*)

*do pecuniam cui ancilla dat aquam* (dative : i-object – *do cui* parallel to *cui ancilla dat*)

But Ovid has *cui dicas* (*cui* depending on *dicas*) as direct object of *elige*, and opens the way for ALP to start producing sham dummy nps. One solution is obviously to say good-bye to Ovid and concentrate on more straightforward constructions.

If we don't (the case of ALP so far...), then we shouldn't be too surprised to see spurious parses get the better of more simple ones.

The case in point is that of *uestigia adsunt eorum quos diligimus*, adapted from a passage in Cicero, *De Legibus*.

ALP used to register a spurious parse with a weight of approximately 1, and the correct one with a weight of -1. The incorrect one gets a heavier weight because it assigns a richer argument structure, that associated with *adsum* meaning *assist*, which has a dative cplt (the spurious np to which *quos* is attached).

The correct and simpler parse is associated with *adsum* meaning *be present*, which is content with a subject.

If we are ready to abandon Ovid, the problem disappears, the building of the spurious dative np is out, because it can't share the accusative of *quos*, or the accusative of *quos* can't share the dative of the spurious np.

Here are the two parses, the wrong one and then the correct one :

[0/uestigia,1/adsunt,2/eorum,3/quos,4/diligimus,endpos(5)]

There are traces of those we love. (*Plus the lingering idea that they are a kind of help, right?*)

The real solution is to keep Ovid with us but at the same time prevent over-generation. We have to adjust the restrictions we put on the case assignable to the dummy NP with respect to the case of the relative pronoun. In ALP 196 we impose the following restrictions :

*constraint([case:Case\_NP],[case:or([nom,acc,abl,Case\_in\_Rel]))],*

i.e. either the relative pronoun and the NP are assigned the same case, or the dummy NP is subject (*nom*), object (*acc*) or subject in an ablative absolute (*abl*).

*Elige cui dicas : tu mihi sola places*<sup>8</sup> (case is not shared ; dummy NP is object)

*Habes in Anglia qui de tuis scriptis optime sentiant*<sup>9</sup> (case is not shared ; dummy NP is object)

*Falluntur quibus luxuria specie liberalitatis imponit*<sup>10</sup>. (case is not shared ; dummy NP is subject)

*Moti qui remanendo impudentiam paupertati adicerent*<sup>11</sup>. (case is shared : nominative)

*Non est onerosum quo utaris ipse communicare cum pluribus*<sup>12</sup> (case is not shared ; dummy NP is object)

*... caesis qui restiterant*<sup>13</sup> (case is not shared ; dummy NP is subject in the AA)

*quibus deerat inimicus per amicos oppressi*<sup>14</sup> (case is not shared ; dummy NP is subject)

*Vestigia adsunt eorum quos diligimus*<sup>15</sup>. (in the reading where *adesse* means *assist* and requires a dative on its cpl arg, case is not shared; dummy NP cannot be subject or object, and thus is not created ; *quos diligimus* is parsed as a standard relative clause with antecedent *eorum* and *eorum quos diligimus* is a genitive attached to *vestigia*, which is assigned subject status with respect to *adsunt*, with *be-present* reading of *adesse*).

The top parse assigned by ALP is now the right one.

```

It should be obvious, however, that in understanding an utterance we bring much more than knowledge of lexis and grammar. However sophisticated our weighting procedures, there will be cases where a funny reading is given priority over the one we might well believe to be the only one available. Here too, relatives lacking an antecedent are likely to lead ALP astray. Consider

*consul ... tresviros quae supplicium postulabat parare iubet* (Sallustius, Cat., 55, 1)

Morphologically, *quae* is a bit of a headache :

An overloaded relative pronoun:

```
lex(quae, relative, [pos:relative, txt:quae, lex:relnomfemsing,gender:fem,
    case:nom, number:sing, function:[subject]]).
lex(quae, relative, [pos:relative, txt:quae, lex:relnomfempl,gender:fem,
    case:nom, number:pl, function:[subject]]).
lex(quae, relative, [pos:relative, txt:quae, lex:relnomneuterpl,gender:neuter,
    case:nom, number:pl, function:[subject]]).
lex(quae, relative, [pos:relative, txt:quae, lex:relaccneuterpl,gender:neuter,
    case:acc, number:pl, function:[object]]).
lex(quae, relative, [pos:relative, txt:quae, lex:relaccneuterpl,gender:neuter,
    case:acc, number:pl, function:[subject]]) % accusative subject in non-finite clauses
```

When there is no antecedent to be found, all five 'readings' are ready to come into play. Perhaps we can feel sympathy for Ahlberg who, seeing an *ad* in front of *supplicium* in a number of manuscripts, proposed to read *quae ad supplicium postulabantur*, a *lectio* to which it would be much easier for ALP to assign an undisputable parse. But, following modern editions, let's stick to *quae supplicium postulabat*.

*Quae supplicium postulabat* : the one (a woman or a girl) who requested the torture  
*quae supplicium postulabat*, in the nominative, can be the object of *parare* ; in the absence of *consul*, it could also be the subject of *iubet*.

Those readings are far-fetched... for a human reader. A human reader has understood 99% of the utterance before he hears or reads it – that is not the case for ALP, which comes up with the right reading (since it is of course of impeccable grammaticality), but prefers the reading where the girl is asking for torture...

The correct parse is to be found below ; it is assigned a weight of 9 and comes in fourth position.

One can be tempted to work on restrictions imposed on the args of *parare* and *postulare*. *Postulare* is happy with human and non-human subjects. We might distinguish between *request* (human subject) and *require* (non-human subject), but such a distinction does not lead to exclusion or even preference :

```

% POSTULARE
lexarg(postulare,
  arglist:[ws(postulo_request,tr_cod,clause:[],mwuw:0,
    args:[subject:[type:np,oblig:yes,constraints:[sem:[hum]]],
      prep_cplt:[type:pp,oblig:no,constraints:[prep:ab]],
      object:[type:pred,oblig:yes,constraints:[type:finite,gap:[],mood:subjunctive]]]),
    ws(postulo_require,tr_cod,clause:[],mwuw:0,
      args:[subject:[type:np,oblig:yes,constraints:[sem:[thing]]],
        object:[type:np,oblig:yes,constraints:[case:acc]]]),
    ws(postulo_request,tr_cod,clause:[],mwuw:0,
      args:[subject:[type:np,oblig:yes,constraints:[sem:[hum]]],
        object:[type:np,oblig:yes,constraints:[case:acc]]])]).

```

*Parare* can likewise take both human and non-human objects :

```

% PARARE
lexarg(parare,
  arglist:[
    ws(paro_prepare,tr_cod,clause:[],mwuw:0,
      args:[subject:[type:np,oblig:yes,constraints:[sem:[hum]]],
        object:[type:np,oblig:yes,constraints:[case:acc]],
        prep_cplt:[type:pp,oblig:no,constraints:[prep:ad]] ])).

```

The semantic constraint on the subject is of no help for the problem discussed here. The subject of *parare* is *tresviros* in the interpretation we would have liked to be able to downgrade.

A final point : note that in the analysis of an AA of the type *caesis qui restiterant* ALP opts for a depth level where *qui restiterant* is parsed as objet of *caedere* (the deep object reading is retrieved by undoing the reorganization of the args performed by the passive voice) :

```

ablativ_absolute
  * caesis * * qui * * restiterant *

## Writing and grammar : not always hand in hand

Julien Gracq writes (in *en lisant en écrivant*, José Corti, Paris, 1980, p. 254) : *J'ai toujours eu tendance, quand j'écris, à user de l'élasticité de construction de la phrase latine, ne me souciant que de façon très cavalière, par exemple, de la proximité du pronom relatif et du substantif auquel il renvoie. Et guère davantage du certificat d'état-civil, au sens étroitement grammatical, qu'on exige du pronom personnel il ou elle.*

Gracq rightly feels that Latin is considerably more cavalier than French with respect to rules. Rules are there as a skeleton which the flesh of writing must somehow take account of, but the flesh is strong in its weakness, and knows that man is eager to make meaning. After all, when programming, we are all in favour of DWIMs (Do What I Mean, not what I say).

Writing a parser entails relying on rules. If a writer doesn't care too much about how he writes because he is sure that the intended meaning will come through whatever the rules say, or, as is the case here, a logical link is standardly dropped, then the parser is likely to go awry by sticking to the rules it necessarily embodies to bring order into what is written.

One example will have to suffice. Erasmus writes (*Letter to Josse Jonas*, 183)

*An eum me putatis qui ob pecuniam **sim** suppressurus Evangelicam veritatem ?*

I don't think anybody (who knows Latin) has any problem understanding what Erasmus means. But ALP thinks Erasmus ought to have written :

*An eum me putatis qui ob pecuniam **sit** suppressurus Evangelicam veritatem ?*

Following the same 'rule' we find *ego non is sum qui mortis periculo magnopere **terrear*** (First Latin Reader) and *Ego is sum qui illi concedi **putem** utilius esse quod postulat* (Cic., Ad Att., VII, 5, 5)

We cannot let our grammar be too lax : we would pay a heavy price in overgeneration and spurious analyses.

ALP, as one would expect, comes up with the following parses :

[0/an,1/eum,2/me,3/putatis,4/qui,5/ob,6/pecuniam,7/**sim**,8/suppressurus,9/euangelicam,10/ueritatem

```

Obviously, Erasmus writes *sim* and means *sit*, because that's the way Latin puts it, logic notwithstanding. He probably wasn't even aware that he did not exactly mean what he wrote ... or wrote what he meant. He would simply retort : *quod scripsi, scripsi - latine loquor*... And he would be right, of course. A tautology a day...

## Features in ALP : a brief and partial survey

### Lexical Features

#### Verbs

*verb([v(conscire,4,consci,consciu,conscit)],tr\_cod,std).*  
*verb([v(cadere,3,cad,cecid,cas)],intr,std).*  
*verb([v(canere,3,can,cecin,cant)],tr\_cod,std).*  
*verb([v(uti,3,ut,us)],tr\_cod\_abl,dep).*

*verb([v(Infinitive, Conjugation Class, RootPres, RootPerf, RootSup)], Class, Type)*

*tr\_cod* applies to transitives with direct object, which can undergo passivisation and form -ndum gerunds (*canitur a X, canendum*)

Type is *std* (standard) or *dep* (deponent)

#### Adjectives

*adj(beat,beat,1,std,n:hpl,[beat,beatissim],[ ]).*  
*adj(cupidus,cupid,1,std,n:hpl,[cupid,cupidissim],[hum]).*  
*adj(facilis,facil,2,std,n:no,[facil,facillim],[ ]).*

*adj(Nominative masc sg, Root, Class, n feature, [Root Comp, Root Sup], [Semantics])*

The *n:Value* feature is meant to capture the availability of the adj as a noun :

n:no - cannot be read as a noun e.g. *aureus*

n:yes - can always be read as noun e.g. *clarus*

n:n - only neuter gender readable as noun: *uerum / uera*

n:hpl - readable as a noun if both plural and with human reference : *boni*

#### Nouns

*noun(1,fem,copiae,copi,class:common, ab:mm, sem:[hum],[nb:pl]). % pluralia tantum*  
*noun(1,fem,ecclesia,ecclesi,class:common, ab:no, sem:[hum, thing,loc],[ ]).*  
*noun(2, masc, morbus, morb, class:common, ab:mm, sem:[abstract, thing],[ ]).*  
*noun(2, neuter, beneficium, benefici,class:common, ab:mm, sem:[abstract, thing],[ ]).*  
*noun(3,masc,orator,orator,um,class:common, ab:no, sem:[hum],[ ]).*  
*noun(4,masc,metus,met,class:common, ab:mm, sem:[abstract],[ ]).*  
*noun(1,masc,catilina,catilin,class:proper,ab:no, sem:[male],[nb:sg]).*

*noun(Declension class, gender, nominative, root, class, ab feature, semantics, restriction on number.*

The *ab* feature specifies use as adjunct in the abl without prep (*mm* : manner means : *morbo*).

Names have got *proper* as value for the class feature, standard nouns have *common*

## Pronouns (and related adjectives)

```
lex(nos, prpers, [pos:prpers, txt:nos, lex:pp1pl,
                 number:pl, person:1, gender:or([masc,fem]),
                 case:acc, sem:[hum]]).
```

lex(Textual form, POS, Feature List)

The Feature List is an open structure, being a list (i.e. it does not have to have the same number of elements throughout) It includes features for POS, Textual Form, lex value (compacted info on features, such as here *pp1pl*, personal pronoun first person plural), number, person, gender, case, semantics, etc.

Examples :

UTRUMQUE

```
lex(utrumque, adj, [pos:adj, txt:utrumque, lex:uterque, gender:neuter, type:tool,
                  case:nom, number:sing]).
lex(utrumque, adj, [pos:adj, txt:utrumque, lex:uterque, gender:neuter, type:tool,
                  case:acc, number:sing]).
lex(utrumque, adj, [pos:adj, txt:utrumque, lex:uterque, gender:masc, type:tool,
                  case:acc, number:sing]).
```

MULTI, MULTAE, MULTA as pronoun

```
lex(multi, prindef, [pos:prindef, txt:multi, lex:multi, gender:masc, person:3, sem:[hum],
                   case:nom, number:pl, function:[subject]]).
lex(multae, prindef, [pos:prindef, txt:multae, lex:multi, gender:fem, person:3, sem:[hum],
                   case:nom, number:pl, function:[subject]]).
lex(multa, prindef, [pos:prindef, txt:multa, lex:multi, gender:neuter, person:3, sem:[thing],
                   case:nom, number:pl, function:[subject]]).
lex(multa, prindef, [pos:prindef, txt:multa, lex:multi, gender:neuter, person:3, sem:[thing],
                   case:acc, number:pl, function:[subject]]).
lex(multa, prindef, [pos:prindef, txt:multa, lex:multi, gender:neuter, person:3, sem:[thing],
                   case:acc, number:pl, function:[object]]).
```

QUIBUS as interrogative pronoun

```
lex(quibus, print, [pos:print, txt:quibus, lex:quis, gender:or([masc,fem,neuter]),
                  case:dat, number:pl, person:3, sem:_,
                  function:[i_object]]).
lex(quibus, print, [pos:print, txt:quibus, lex:quis, gender:or([masc,fem,neuter]),
                  case:abl, number:pl, person:3, sem:_,
                  function:[prep_cpl]]).
```

Note the use of the OR operator in feature values: or([List\_of\_Possible\_Values]) and of the *anonymous variable* ( *\_* ) to indicate that any value is to be accepted.

## Prepositions

```
lex(a, prep, [lex:ab, pos:prep, requires:abl, gerund:no, type:pre]).
lex(ab, prep, [lex:ab, pos:prep, requires:abl, gerund:no, type:pre]).
lex(abs, prep, [lex:ab, pos:prep, requires:abl, gerund:no, type:pre]).
lex(ad, prep, [lex:ad, pos:prep, requires:acc, gerund:yes, type:pre]).
```

lex(Textual Form, POS, List of Features (includes lexeme, POS, Required Case, availability for gerunds, type (*pre* or *post* governed np : think of *causa*))

## Adverbs

*lex(ceterum, adv,[lex:ceterum, pos:adv,type:clausal, sem:discourse]).*

*lex(cotidie, adv,[lex:cotidie, pos:adv,type:vpbound, sem:time]).*

*lex(cras, adv,[lex:cras, pos:adv,type:vpbound, sem:time]).*

*lex*(Text Form, POS, Feature List (includes preferred attachment – vp or whole clause – and semantics))

## Subordinators

*lex(quoniam, sub,[lex:quoniam, pos:sub, argbound:no, mood:\_, value:reason]).*

*lex(quia, sub,[lex:quia, pos:sub, argbound:no, mood:\_, value:reason]).*

*lex(quod, sub,[lex:quod, pos:sub, argbound:no, mood:\_, value:reason]).*

*lex(quando, sub,[lex:quando, pos:sub, argbound:no, mood:\_, value:reason]).*

*lex(quin, sub,[lex:quin, pos:sub, argbound:yes, mood:subjunctive]).*

*lex(quominus, sub,[lex:quominus, pos:sub, argbound:yes, mood:subjunctive]).*

Note the *argbound* feature, with values *yes/no*, to specify whether the subordinate clause can be read as argument. *Mood* and *value* are straightforward. As the feature list is a list, it can include features that are sometimes specified and sometimes not. The *value* feature is a case in point. The *mood* feature has to be present (for use by the *constraint* predicate) but the value can be left open by means of the *anonymous variable*.

## Particles

*lex(ne\_int, part, [lex:ne\_int, type:int, value:open\_orientation, clausetype:\_]).*

*lex(num, part, [lex:num, type:int, value:open\_orientation, clausetype:sub]).* % in indirect questions

*lex(num, part, [lex:num, type:int, value:negative\_orientation, clausetype:main]).* % in direct questions

*lex(nonne, part, [lex:num, type:int, value:positive\_orientation, clausetype:\_]).* % in direct questions

Note the *ne\_int* as textual form ; it is produced by the *word list maker*, which removes it from the element it is attached to (the process makes sure that any word ending in *-ne* is preserved as an alternative reading (*agmine*, *sine*, etc, etc. - see also the treatment of *que* and *ue*).

The *value* and *clausetype* features are straightforward.

## Verb templates

The *lexarg* structures are essential to the working of ALP. Whenever an *arg-bearer* (all verbs, but also some nouns and adjectives) is encountered, ALP gets hold of its *arglist*, which is made up of *ws* (word sense) structures. Each word sense is specified by a short description in the guise of a rough English equivalent, followed by its transitivity class, restrictions that apply on the clause it is inserted in (most of the time the restriction list is empty, but see *dubitare* below), and its weight as potential multi-word unit. There follows a list of arguments as value of the *args* feature. Each argument is specified as to its grammatical function, its obligatory or optional character, with a list of constraints that the constituent building the argument must meet : the *type* is one such constraint, but there is also a specific *constraints list* which, being a list, is open as to number and nature of the individual constraints.

```
% REDDERE
lexarg(reddere,
  arglist:[ws(reddo_give_back,tr_cod,clause:[],mwuw:0,
    args:[subject:[type:np,oblig:yes,constraints:[sem:[hum]]],
      object:[type:np,oblig:yes,constraints:[case:acc]]]),
    ws(reddo_make,tr_cod_cplt,clause:[],mwuw:0,
      args:[subject:[type:np,oblig:yes,constraints:[sem:[hum]]],
        object:[type:np,oblig:yes,constraints:[case:acc,number:N,gender:G]],
        object_cplt:[type:adjp,oblig:yes,constraints:[case:acc, number:N,gender:G]]]])).

% REGNARE
% Tres annos regnavit.

% DUBITARE
lexarg(dubitare,
  arglist:[ws(dubito_doubt,tr,clause:[polarity:neg],mwuw:0,
    args:[subject:[type:np,oblig:yes,constraints:[sem:[hum]]],
    object:[type:pred,oblig:yes,constraints:[type:finite,gap:[],mood:subjunctive,
      argbound:yes, subordinator:quin]]]),

    ws(dubito_hesitate,tr,clause:[polarity:neg],mwuw:0,
    args:[subject:[type:np,oblig:yes,constraints:[sem:[hum]]],
    object:[type:pred,oblig:yes,constraints:[type:nonfinite_i]]]),

    ws(dubito_doubt,tr,clause:[illocutionary_force:question],mwuw:0,
    args:[subject:[type:np,oblig:yes,constraints:[sem:[hum]]],
    object:[type:pred,oblig:yes,constraints:[type:finite,gap:[],mood:subjunctive,
      argbound:yes, subordinator:quin]]]),

    ws(dubito_hesitate,tr,clause:[illocutionary_force:question],mwuw:0,
    args:[subject:[type:np,oblig:yes,constraints:[sem:[hum]]],
    object:[type:pred,oblig:yes,constraints:[type:nonfinite_i]]])).

```

It should be noted that nouns too can bear arguments. A case in point is the noun *nuntius* :

*lexarg(nuntius, arg:[type:pred,constraints:[type:nonfinite]])*.

The *lexarg* predicate associated with *nuntius* specifies that *nuntius* can govern a nonfinite clause ; such args are generally optional. But they need to be accounted for if we wish to parse such a sentence as

*Caecina laetum ex Italia nuntium accipit alam Silianam sacramento Vitellii accessisse.* (Tacitus, Historiarum Liber I, LXX, 1)

where *alam Silianam sacramento Vitellii accessisse* is the nonfinite clause filling in the arg position in the *lexarg* clause associated with *nuntius*.

The parse associated with *ubi <Caesar> illum suis locis se tenere animum advertit* (Caesar, BC, III, 41,2) relies on a similar entry for the relevant word sense of *animus* (i.e. intention) :

There is certainly room for improvement in the treatment of arguments of nouns in the available lexicographical tools (TLL, Lewis and Short, Forcellini, Gaffiot,...).

## General Features

*Pathlist* : the word-list maker, the Prolog subprocedure that turns an ASCII string into a wordlist, produces and records (with *recorda*) a number of *position* structures (*position* being a functor with arity three, i.e. with three arguments) in a storage space (a box) named *pos* :

```
recorda(pos,position(Pos,Posand1,NewHead),_),
```

It should be noted that in the above the small-letter *pos* is an atom (short for *position*), to be carefully distinguished from the variable *Pos*, which is meant to store the position reached in the string by the word-list maker (1, 2, 3, etc.)

A general lexical rule will use the records so produced to store the words under their respective POS (Part of Speech, this time), using the lexicon's *lex* clauses (mainly produced by *makelex.pl*), to get at the relevant POS.

In the *wordforms* file (produced by *makelex*) we find such a clause as :

```
lex(ambulant, v, [pos:v, class:intr, type:finite, lex:ambulare, voice:act, txt:ambulant, tense:imperfect, kind:std, mood:subjunctive, number:pl, person:3]).
```

Using such clauses we map the words in the relevant Part of Speech boxes :

```
[lex,words] --->[recorded(pos,position(A,B,Word),_),
% we have the word form Word in the string, e.g. ambulant
lex(Word,Box,FS),
% we have a lex for the Word (ambulant) to put in the relevant Box (the v Box)
% accompanied by the Feature List (FS) stored in the lexicon
map(Box,[from:A,to:B|FS])].

% we store its position there accompanied by the feature list FS (third arg of lex)
```

We can then use the stored record to build the *pathlist* ; in the simple case of a one word structure we use the *from:P1* and *to:P2* features to build a pathlist containing a single element : *pathlist: [p(P1,P2)]* as in the mapping of an adjective phrase made up of a single adjective :

```
lex(formosam, adj, [pos:adj, txt:formosam, lex:formosus, type:std, n:no, case:acc, gender:fem, number:sing, degree:pos, sem:[]]).
```

```
[adj,adjp1] --->
[mapped(adj,[from:A,to:B|FS]),
constraint([case:C, number:N, gender:G, type:Type, lex:Lex],FS),
map(adjp,[cat:adjp,pathlist:[p(A,B)],distance:[0],hp:[p(A,B)],
case:C,number:N, gender:G,lex:Lex,type:Type,w:1,constituent_structure:Lex])].
```

When we build larger structures we join the pathlists, and perform the necessary checks on the resulting longer paths : computing distance, checking adjacency or near-adjacency, or conditioned near-adjacency, etc.

We also work out where the *head* lies and store the path pertaining to the head as value of the *hp* (head phrase) feature. In the case of a one word structure, *pathlist* and *hp* store the same value.

Note how the *constraint* predicate is used in the rule above to retrieve values for features stored in the lexicon : case, number, gender, etc are read off the lexical entry and can then be stored in the new structure to be mapped, namely the adjective phrase. We use *constraint* in order not to have to bother about the order the feature-value pairs are stored, nor about there being a fixed number of elements in the FS list. Using the straightforward unification clause :

*FS = [pos:\_, txt:\_, lex:Lex, type:Type, n:\_, case:C, gender:G, number:N, degree:\_, sem:\_]*

is considerably more error-prone and the program should have to be revised when a feature is added to a standard feature list or deleted from it.

To see the pathlists at work we can look at the link between adj and noun ; or between two noun phrases, as is the case of an np resulting from a core np to which is joined an np in the genitive acting as 'complément déterminatif' to use the terminology prevalent in secondary school classes when I was a pupil struggling with Caesar and, later, Virgil.

Consider

% 115 Tacitus Hist V 2 1.

*Quoniam famosae urbis supremum diem tradituri sumus congruens videtur primordia eius aperire.*

It seems obvious that *famosae urbis* should be attached to *supremum diem* and *eius* to *primordia*, rather than, for instance, the other way round. A check on adjacency should be sufficient here, with the order 'cplt followed by np head' (*famosae urbis supremum diem*) in the first case, and the reverse order in the second (*primordia eius*). But can we be sure that no element can come and get stuck between the two nps ? Of course, we can't, as any reader of Latin poetry is well aware. There has to be a check on the number and nature of the intervening elements. If we have available the pathlists of the two nps and the pathlists of their heads, we can specify conditions such as those specified in the np25 rule :

```
[[finite,np25] --->
[mapped(np,Fnp1), % the head
mapped(np,Fnp2), % the noun cplt

Fnp1 \= Fnp2, % not the same NP

constraint([pathlist:PL1, hp:[p(H1,H2)],distance:[Distnp1],sem:Sem,w:W1,
number:Nb,person:3,gender:G,case:C,class:common,lex:LexNoun], Fnp1),

constraint([pathlist:PL2, hp:[p(G1,G2)],distance:[Distnp2],w:W2,case:gen],Fnp2),
% case must be genitive

distancev(PL1,PL2,Strain),          Strain < 2,
% distance between paths  one word max !!!
distancev([p(H1,H2)],[p(G1,G2)],Strain2), Strain2 < 3,
% distance between heads  two words max !!!

....
```

*Distance and weight (w)*

The *distance* feature houses the distance (in terms of number of intervening words) between two constituents. If the constituents are expected to be adjacent, the distance factor is a strain which renders computability of the intended construct lower, i.e. the constituent will be harder to parse (for the human reader, not ALP!). Such strain decreases the probability of the parse in the competition with other candidate parses. It is the negative counterpart of *weight*. The value of the weight feature increases with the postulated links posited by the parser.

*Constituent\_structure*

The value of this feature is a bit of the parse tree, or the entire parse tree once we reach the top level, i.e. have a complete parse for a whole sentence. The different bits are linked to one another by inclusion or contiguity. One should remember that the value assigned to a feature can display any

level of complexity. This is why the raw parses and their pretty-printed counterparts can be the values assigned to the *constituent\_structure* feature at sentence level.

### *Cat*

The *cat(egory)* feature is easy to understand and of course very handy to retrieve from the mapped structures the ones we are interested in (an np, a pp, a subordinate clause, etc)

### *Class and Type*

These features allow for a subclassification of the main constituents according to the needs of the parsing procedure. The assignments are likely to be modified or added to as the parser develops.

# Grammatical Features

## Adjective Phrases

Example :

```
map(adjp,[cat:adjp,pathlist:Sorted,distance:Distance,hp:[p(A,B)],
case:Case,number:N,gender:G,degree:comp,lex:Lex,type:Type,w:Weight,
constituent_structure:[Lex,comp_cplt:FSnp]]).
```

The feature list shouldn't come as a surprise at this stage of our presentation. The feature *degree* is restricted to adjectives and adverbs

example : *grande* in *dedimus grande patientiae documentum*

```
adjp:[cat:adjp,pathlist:[p(1,2)],
distance:[0],hp:[p(1,2)],case:acc,number:sing,gender:neuter,lex:grandis,
type:std,w:1,constituent_structure:grandis]]
```

Remember that the word count in the word list starts at zero, so that the rank of the word is given by the second element of the p structure : *grande* is the second word so that we have  $p(1,2)$  as constituent of its pathlist.

## Noun Phrases

Example

```
map(np,[pathlist:Sorted,hp:[p(A,B)],index:i(p(A,B)),distance:[Distance],
cat:np,class:Class,sem:Sem,
number:Nb,person:3,gender:Gender,type:core,lex:LexNoun,lextype:full,
case:CaseOut,w:Weight,
constituent_structure:[head:FSnounp,adjp:FSadj]]).
```

We ought to say a word about the *index* feature, which we observe to coincide with the path assigned to the head of the noun phrase. We have  $hp:[p(A,B)]$  and  $index:i(p(A,B))$ . The index points to the position of the head in the np and will be used to associate a gap with its filler. In *rex quem regina amat*, the gap in the clause *regina amat*, i.e. the direct object of *amat* is associated with *rex* by way of relative *quem*.

The gap disappears when the entire sentence is parsed. In *rex quem regina amat amat ancillam*, the gap gets filled by its association with *quem* and the link between *quem* and *rex* is licensed by syntactic rules and semantic restrictions.

Example of np : n and adj

(*populi Romani* in *Non debes temere consulem populi Romani saltatorem vocare*)

```
noun_cplt:[pathlist:[p(4,5),p(5,6)],hp:[p(4,5)],
index:i(p(4,5)),distance:[0],cat:np,
class:common,
sem:[hum],number:sing,person:3,
gender:masc,type:core,lex:populus,
lextype:full,case:gen,w:2,
constituent_structure:[head:[pathlist:[p(4,5)],pos:noun,
txt:populi,lex:populus,case:gen,gender:masc,class:common,
ab:no,number:sing,sem:[hum]],
adjp:[cat:adjp,pathlist:[p(5,6)],distance:[0],
hp[p(5,6)],
case:gen,number:sing,gender:masc,lex:romanus,
type:std,w:1,
constituent_structure:romanus]]]]]
```

## Prepositional Phrases

### Example

```
map(pp,[pathlist:Sorted,hp:[p(Begin,End)],distance:Dist,index:Inp,
case:Case,prep:Lexprep, sem:Sem,lex:LexNoun,
w:Weight,
type:Type,
% the type is the NP type, not the prep's
% it will be available for checks on the NP within the PP
% for instance in adjuncts
% (Type registers whether the NP is interrogative)
cat:pp,constituent_structure:[prep:Lexprep,head:Fnp]]).
```

Example (pretty-printed) : (*cum voce in Memoriam quoque ipsam cum voce perdidissemus si tam in nostra potestate esset oblivisci quam tacere.*)

```
prep_phrase_adjunct_1
* cum * * uoce *
index:i(p(3,4))
case:abl
prep:cum
sem:[abstract]
lex:uox
cat:pp
constituent_structure
  prep:cum
  head
    * uoce *
    index:i(p(3,4))
    cat:np
    sem:[abstract]
    number:sing
    person:3
    gender:fem
    lex:uox
    case:abl
    constituent_structure
      uoce
```

## Adjuncts

### Example

```
map(adjunct,[pathlist:[p(X,Y)],hp:[p(X,Y)],distance:[0],
cat:np,class:adjunct,value:place,
number:Nb,person:3,gender:Gender,lex:Lexnoun,lextype:full,type:place,
case:gen,w:2,
constituent_structure:[head:[lex:Lexnoun, sem:location,cat:np,number:Nb,gender:Gender,case:gen,index:i(p(X,Y))]]]).
```

Example of an np adjunct in the genitive (locative) and with *type:place*

*Sum Lugdini.*

```
adjunct:[pathlist:[p(1,2)],hp:[p(1,2)],distance:[0],cat:np,
class:adjunct,value:place,number:sing,person:3,gender:neuter,lex:
lugdunum,lextype:full,type:place,case:gen,w:2,constituent_structure:
[head:[lex:lugdunum,sem:location,cat:np,number:sing,gender:neuter,case:
gen,index:i(p(1,2))]]]
```

## Verb Groups

### Examples

```
map(vgpos,[cat:vg,type:finite,pathlist:Sorted,hp:[p(C,D)],lex:Lex,
        person:P,mood:Mood,tense:Tenseout,voice:act,
        number:Nb,gender:G,w:5])).
```

```
map(vgpos,[cat:vg,type:nonfinite,pathlist:Sorted,hp:[p(C,D)],lex:Lex,
        person:_,mood:infinitive,tense:perfect,
        voice:act,number:Nb,gender:G,w:3])).
```

### Example : *venisses* in *si venisses laetus fuisset*

```
vg:[selected_reading:uenio_come,polarity:pos,cat:vg,pathlist:[p(1,2)],hp:
[p(1,2)],gender:_85492,w:0,pos:v,class:intr,type:finite,lex:uenire,kind:
std,mood:subjunctive,voice:act,txt:uenisses,tense:pluperfect,number:sing,
person:2]
```

## Clauses

ALP parses finite and non-finite clauses (infinitives, gerundial, supine-based, participial), main and subordinate clauses, with positive or negative polarity, declarative and interrogative. It also parses relative clauses and links them with the antecedent (when there is one).

The *argbound* feature (with values *yes* or *no*) records whether a clause fills in the arg of a predicate (as in *timeo ne* + Clause, *non dubito quin* + Clause, *puto* + accusative-cum-infinitive,...) or is free (*cum se diceret indicaturum de coniuratione, ubi paulatim licentia crevit*,...)

### Examples

```
map(pred,[cat:pred,type:nonfinite_i,
        mood:supine,tense:present,class:m,
        pathlist:Sorted,distance:[Distance],
        number:sing,gender:neuter,case:or([nom,acc]),
        person:3,
        gap:[],w:Wtotal,
        constituent_structure:[vg:FSverbfull|ST]]).
```

```
map(pred,[cat:pred,
        type:finite,
        pathlist:NSortedF,
        distance:[Distance],
        illocutionary_force:Force,
        class:m,
        number:sing,           % nber, gender, and person of the CLAUSE, not its subject
        person:3,vgperson:Psubj, % needed in imperative clauses of the first and second persons
        gender:neuter,
        mood:Mood,
        tense:Tense,
        polarity:Pol,
        argbound:no,
        gap:Gap,
        w:Wtot,
        add:Add,
        checkint:Interrogative,
        flagint:Flagint,
        constituent_structure:[illocutionary_force:Force,vg:FSverbfull|ST]]).
        % ST is the sorted list of arg fillers
```

```

map(relative_clause,[pathlist:PL,
                    distance:Distance,
                    gap:GAPARG,      % gap info carried by the clause
                    index:Index,
                    number:Nb,
                    gender:Gender,
                    case:Case,
                    person:PersonRel,
                    retype:Rel_type,
                    type:finite,
                    mood:Mood,
                    tense:Tense,
                    constraints:Constraints,
                    w:Weight,
                    constituent_structure:C_str]) ].

```

We have already discussed the gap feature. The *polarity* feature is recorded to satisfy constraints on the arg (*haud magni facere*, etc.). *Mood* is essential to the description of both subordinate and main clauses (think of conditionals).

Examples are provided by the parses produced by ALP on its test files.

## Using the recorded feature values

The *finiteness* constraint on the *pred* enables us to show only complete parses, i.e. parses for the sentence submitted that make of it an independent gapless (finite) clause.

The 'type:finite' constraint should be lifted in parsing bits of indirect discourse, where a lot of verbs are likely to be infinitives.

```
constraint([cat:pred,
             argbound:no,
             class:m,           % the whole pred is main and not arg-bound
             pathlist:Pathlist,
             type:finite,       % the finiteness constraint
             distance:[Distance], % Distance and Weight used in ranking
             gap[],             % no gap left
             w:Weight,
             constituent_structure:Parse], % the value of the constituent_structure feature is the
parse shown to the user, in raw and pretty-printed format %
Pred), % all the above constraints apply to a candidate clause
```

## Appendix I ALP reads Augustine ... during a coffee break

AUGUSTINE GOES TO CHURCH TO BUY THE SERVICES OF A PROSTITUTE

Conf. 3, III,5, 6-9 Budé 1933 de Labriolle

*"Ausus sum etiam in celebritate sollemnitatum tuarum intra parietes ecclesiae tuae concupiscere et agere negotium procurandi fructus mortis"*

De Labriolle: "N'ai-je pas osé, en pleine célébration de vos solennités, dans l'enceinte de votre église, convoiter des fruits de mort et négocier le moyen de me les procurer?" (qu'en termes élégants...)

Arnaud d'Andilly: "Mon impudence passa même jusqu'à ce point, qu'en l'une de vos fêtes les plus solennelles, et dans votre propre église, j'osai concevoir un désir damnable et ménager un accord funeste qui ne pouvoit produire que des fruits de mort."  
(no marks for concision...)

William Watts (Loeb Classical Library): "I was so bold one day, as thy solemnities were a celebrating, even within the walls of thy Church, to desire and to execute a business, enough to purchase me the very fruits of death."  
(not very clear...)

De Labriolle (rightly, it seems to me) parses 'fructus mortis' as the object of both 'concupiscere' and 'procurandi' - that's well beyond the power of ALP !!!

We use a somewhat simpler version:

*Ausus sum in ecclesia tua concupiscere fructus mortis et agere negotium procurandi eos.*

[0/ausus,1/sum,2/in,3/ecclesia,4/tua,5/concupiscere,6/fructus,7/mortis,8/et,9/agere,10/negotium,11/procurandi,12/eos,endpos(13)]

cputime : 207 sec i.e. over three minutes ! (ALP 202)

Such a result is to be seen in an optimistic light – ALP plods on, but comes up with a correct parse. Much better than just giving up, or, worse, turning out rubbish.

It should be kept in mind that the most time-consuming phrases (in terms of parsing, of course) are the ones that are not bound to any argument but function as clause-level adjuncts. As a general rule, a fifteen-word limit imposed on strings to be parsed seems reasonable. Consider the following data based on Livius, *Ab Urbe Condita*, Liber XXI, 8:

*Per totum tempus hiemis quies inter labores iam exhaustos aut mox exhauriendos renovavit corpora animosque ad omnia de integro patienda.*

*Quies renovavit corpora animosque.*

5 words

cputime : 0.08

*Quies inter labores renovavit corpora animosque.*

7 words

cputime : 0.7

*Quies inter labores renovavit corpora animosque ad omnia patienda.*

10 words

cputime : 15.5

*Quies inter labores renovavit corpora animosque ad omnia de integro patienda.*

12 words

cputime : 18.7

*Quies inter labores exhaustos aut exhauriendos renovavit corpora animosque ad omnia de integro patienda.*

15 words

cputime : 74.53125000000001 i.e. over a minute

The parses produced I believe to be correct. Here is the one associated with the 15-word string:

(version : alp198)

## Appendix II How to Use ALP

### Running ALP

ALP is made up of three SWI-Prolog programs :

*alpxxx.pl* : main program (xxx to be replaced by version number, e.g. alp199.pl)

*frames.pl* : lexical entries for *argument bearers*, mainly verbs

*makelex.pl* : program building *wordforms*, i.e. the morphological variants needed by ALP

Once SWI-Prolog has been properly installed, ALP is ready for use.

Both *alpxxx* and *makelex* are executables, with a GO step. To execute the programs, simply type in : *go.* (don't forget the final dot). In the case of *makelex*, press the *Enter* key once the system has replied with '*true*'.

To get out of a Prolog session, type : *halt.* (again, don't forget the dot!)

On execution, ALP will load both the *wordforms* produced by *makelex.pl* and the *frames.pl* file, provided the files are reachable by ALP.

The easiest way to use ALP, therefore, is to have a single directory containing both the executable files (*alpxxx.pl* and *makelex.pl*), the *frames.pl* file, the *wordforms* and the test files that one wishes to submit to the parsing process.

If no testfile is available, *stdin* can be used as input stream. The sentences one wishes to parse are then to be entered directly from the keyboard, and should end with either a *dot*, a *question mark*, or a *slash* (see below). To get out of the input loop type : *stop.* (mind the dot !). And to get out of Prolog, remember : *halt.* (nothing to say about the dot?)

The test file names should preferably be made up of a single atom, such as *test*, *testfile*, *mytest*, *alptest*, etc.

The test files must end on a line that is made up of the single word *stop* followed by a dot, i.e. *stop.*

The result file name (i.e. the name of the file containing the parses) should also be a single atom, to which the system will add a *.lst* extension. The filename selected by the user for output can therefore be the same as for input (*test* → *test.lst*).

Each sentence in a test file should end with a final punctuation sign, either dot (.), question mark (?), or a slash (/). The question mark is not used by the parser as an indication that it should parse the string as a question. The slash is used for partial structures, as in :

% 20.

*Ut amicitia societasque nostra in aeternum rata sint /*

% 21.

*postulamus a uobis muros coloniae munimenta servitii detrahatis.*

Commas are best left out, unless they are used to isolate an *addressee* (vocative), as in :

*Argiletanas mauis habitare tabernas cum tibi, parue liber, scrinia nostra vacent.  
Incipe, parve puer, risu cognoscere matrem.  
Hanc etiam vix, Tityre, duco.*

Or to guide *distributed* structures as in:

*Contemnunt novitatem meam, ego illorum ignaviam.  
Mihi fortuna, illis probra obiectantur.  
Nulli parietes nostram salutem, nullae leges, nulla iura custodient.  
Insidiatores ab Othone in Germaniam, a Vitellio in urbem missi.  
Versabitur in rostris furor, in curia timor, in foro coniuratio, in Campo miles, in agris vastitas.*

## Settings

The following settings are made available in the ALP settings menu:

### *Depth Level for Finite Pass*

- 1. Shallow % default
- 2. Intermediate
- 3. Deep

### *Type of Parses Displayed*

- 1. Whole Sentences Only % default
- 2. Phrases and Clauses

### *Number of Parses Displayed*

- 0. one parse only
- 1. one parse only, or two if the second parse has the same ranking as the first % default
- 2. two parses, whatever the ranking of the second
- 3. all available parses

**Depth level :** *deep mode* means no limit on the number of *runs* for rules marked as belonging to the *finite* run. Such rules will only stop applying when there is no new production resulting from their application. *Deep mode* entails huge computational costs, and should only be selected to make quite sure that ALP is unable to adequately tackle complex sentences. For instance, relative clauses within relative clauses will tend to be attached higher than they should if the depth level is *shallow* or *intermediate*.

**Type of parses displayed :** if ALP is used on syntactic wholes that do not build complete sentences (for instance because such sentences have been cut up into bits to render the parsing task less formidable), Option 2 (*display of phrases and clauses*) should be selected. Full sentences being clauses, they will get parsed and displayed as such.

**Number of parses displayed :** the default option (2) ensures that only the top ranking parse or parses are displayed. The whole point of the weighting procedure is precisely to make top selection the most reasonable choice. The option *all available parses* is to be selected if it is believed that there is something wrong in the assignment of weight to one or more syntactic groupings.

## Program files

The Prolog programs are *ascii* files, and can therefore be explored with a large number of tools. The editor within SWI-Prolog is a wise choice (type in *edit.* once the program has loaded).

The *wordforms* produced by *makelex* is also an *ascii* file. It can be sorted and explored outside of Prolog. If the sorted file is given a *.pl* extension, it will also be explorable by Prolog :  
*sort wordforms > alplex.pl*

To be able to add vocabulary to ALP one should make a careful study of the lexical items that ALP already features. We should emphasize that there is no point in adding a verb to *makelex* without giving it an argument structure in *frames*. Only then can it be used in a sentence to be parsed (see next section).

## Adding to ALP

To add new grammar rules one has to know both Prolog and ALP rather intimately.  
But adding vocabulary to ALP is quite feasible without having to enter the arcana or bowels of the beast.

Note first that in the vocabulary to be entered in *makelex* no use should be made of letter *v* (*u* is to be used instead) and capital letters are banned. The entry for *Ariovistus* reads :

```
noun(2,masc,ariouistus,ariouist,class:proper,ab:no, sem:[male],[nb:sg]).
```

When entering text to be parsed *v* and capital letters can be used freely :

*Ariovistum se consule cupidissime populi Romani amicitiam appetisse.* (Caesar, BG, I, XL, 1)  
(Note that ALP will recognise *appetisse* as variant of *appetuisse*).

Suppose we want ALP to be able to parse

*Memorabantur exempla maiorum qui iuventutis irreverentiam gravibus decretis notavissent.* (adapted from Tac ANN III 31 4)

Perusing the *makelex.pl* file enables us to add the missing lexical entries (at the time of writing ; obviously the work described here has been integrated into *makelex*)

On the model of

```
noun(1,fem,impudentia,impudenti,class:common, ab:mm, sem:[quality],[ ]).
```

we add:

```
noun(1,fem,irreuerentia,irreuerenti,class:common, ab:mm, sem:[quality],[ ]).
```

and on the model of

```
noun(2, neuter, edictum, edict,class:common, ab:mm, sem:[thing,abstract],[ ]).
```

we add:

```
noun(2, neuter, decretum, decret,class:common, ab:mm, sem:[thing,abstract],[ ]).
```

Similarly, on the basis of

```
verb([v(renouare,1,renou,renouau,renouat)],tr_cod,std). % standard transitive verb first conjugation
```

we create the new lexical entries:

```
verb([v(memorare,1,memor,memorau,memorat)],tr_cod,std).
```

```
verb([v(notare,1,not,notau,notat)],tr_cod,std).
```

The latter, being verb entries, need to be associated with the right template.

Looking at the frames file (*frames.pl*) we find the template for transitive verbs with human subject and adjunct of a specifiable case :

```
lexarg(Xre,
  arglist:[ws(v_v,tr_cod,clause:[],mwuw:0,
    args:[subject:[type:np,oblig:yes,constraints:[sem:[hum]]],
      object:[type:np,oblig:no,constraints:[case:acc]],
      adjunct:[type:np,oblig:no,constraints:[case:CASE]]]])).
```

We use this template to build the template we associate with the *notare* we are interested in:

```
lexarg(notare,
  arglist:[ws(oto_blame,tr_cod,clause:[],mwuw:0,
    args:[subject:[type:np,oblig:yes,constraints:[sem:[hum]]],
      object:[type:np,oblig:yes,constraints:[case:acc]],
      adjunct:[type:np,oblig:yes,constraints:[case:abl]]]])).
```

Note that we have specified the obligatory character of the ablative adjunct, which will help us distinguish between this reading of *noto* and others we might wish to add in the future.

For *memoro* we use the template for transitive verbs with human subject:

```
lexarg(memorare,
  arglist:[
    ws(memoro_recall,tr_cod,clause:[],mwuw:0,
      args:[subject:[type:np,oblig:yes,constraints:[sem:[hum]]],
        object:[type:np,oblig:yes,constraints:[case:acc]]]])).
```

Once the entries have been added to *makelex.pl* and the templates to *frames.pl*, we run *makelex* to build the new *wordforms* file.

1 ?- go.

```
MAKELEX, building vocabulary file for ALP
Expanding the lexical macros...
Done
true .
```

(here we press the Enter key and then stop Prolog with : *halt.*)

*Makelex* has produced a new *wordforms* file, which will henceforth be used by ALP.

We can now run the current version of ALP (*alp187.pl* at the time of writing)

Once ALP is launched, we are ready to enter the sentence when prompted by ALP to do so. We can use *stdin* as input stream to enter the sentence using the keyboard and select a filename for the results (below we specify *additions*, which will result in the production of *additions.lst*, which will house the resulting parse or parses). We shouldn't forget the end dot...

1 ?- go.

ALP, a data-driven feature-unification parser for a subset of classical Latin

Current settings are: DEFAULT. Modify ? (y/n) [here we press *n*]

```
Input file? [stdin. or file_name.] --> stdin.
Output file? [file_name.] --> |: additions.

```

to pick *maiorum* as the antecedent of *qui* and subject of *notauissent*.

## Appendix III Parsing and Word Sense Assignment

On top of revealing syntactic structure a parser should attempt to assign word senses to the lexical items that make up its leaves. It should not stop at the lemmatisation stage, in so far as word sense recognition ties up with structural assignment.

Wordsenses do not exist out there : their status as lexicographical constructs is not in doubt. But recognizing their true nature as constructs should not detract from acknowledging their usefulness in the accomplishment of a number of NLP-oriented tasks, translation being an outstanding example.

As a matter of fact, any description of sense is a construct. There is a lot to be said in favour of keeping the metalinguistic description to a minimum, so that belonging to a WordNet *synset* may be the most adequate way of specifying a wordsense. Each word sense of a lexical item should give rise to assignment to a different synset. The synset glosses should serve for orientation only, and are not to be confused with definitions. Definitions are part of the exploitable lexicographical description, as will be shown below.

A good starting point is an examination of the wordsenses assigned by the body of lexicographical work for a given language, in a monolingual perspective first, but without rejecting a bilingual or multilingual framework (translation-oriented dictionaries).

The question of granularity is likely to be settled by the range and depth of the analysis tools that we are able to devise.

For the items that the parser recognizes as *argument bearers*, we shall need to specify word sense descriptions for the arguments as well as for the arg bearer itself. We shall have to proceed step by step. In a first stage, we suggest that an argument can be described by a *lexical world*, i.e. a set of lemmas gleaned mainly from the examples offered by the lexicographical resources. See below for two wordsenses of *colo* as described in *Forcellini* and *Lewis and Short*.

A *lexical world* should exclude *toolwords* which we can store in a *stoplist*, in order to be able to concentrate on full lexical items. In specific cases, we may wish to register wordforms instead of lemmas, and we should be ready to house descriptions of any degree of specificity in the case of *multi-word units* (phraseological component).

Once our tools are powerful enough, we can use them in a bootstrapping procedure by applying them to the dictionary-registered citations, attempting to bring the granularity level of our analysis down to word senses.

In the parsing process, to work out whether an item in the string to be parsed potentially filling an arg position is to be parsed as filling that position indeed, we have to measure the lexical distance between the item in text and the lemmas belonging to the lexical world assigned to that arg position in the description the parser makes use of.

In the standard case, where the arg bearer has a number of word senses, each word sense will entail a specific description for the args, and the measure of lexical distance should lead to the selection of the appropriate word senses, both at the level of the arg and at that of the arg bearer.

Lexical distance can be equated with the length of the path that needs to be covered for two items to meet along synset and synset-extending relations (hyponymy, etc). In our case, the two items should be pairs resulting from the pairing of the item found in the text to be parsed and each member of the

lexical world associated with the arg under a given wordsense. The lexical distance to be used for decision taking with respect to wordsense selection would be based on a mean value computed on all the pairs.

We would need to specify limits to the exploration of lexical distance. If the two items do not meet on a path of length  $l$  they will be deemed to be unrelated (although they may of course be related at a higher level).

## Two word senses of COLO in Forcellini

*Colo, colare* vs *colo, colere* : the distinction is in most cases to be decided on the basis of lemmatisation ; if necessary (parsing the very form *colo*), on the basis of the object arg. Let's concentrate on *colo, colere*.

We should exploit, not only the examples, but also the definitions and semantic characterization with respect to *habitare, observare, venerari*.

The *lexical worlds* can be hand-crafted or, more roughly, computer-derived. As a matter of fact, if we insert the missing headword in the examples where it does not occur, and decorate it with the appropriate wordsense number, or simply add the wordsense number where the headword occurs, and then build up a concordance excluding stopwords, we would have a most useful tool for specifying the lexical worlds that we have in mind.

Definition : **studium, operam, laborem** pono in re aliqua **perficienda, assiduus** sum circa rem aliquem, **exerceo, excolo, curo**

(It. *lavorare, coltivare, esercitare*; Fr. *travailler, cultiver, soigner*; Hisp. *labrar, cultivar*; Germ. *etwas treiben, betreiben, um etwas herum sein Geschäft treiben*; Angl. *to exercise, labour upon, cultivate*).

We concentrate on the object arg for the two wordsenses that ALP has so far been concerned with :

```
lexarg(colere,
  arglist:[ws(colo_inhabit,tr_cod,clause:[],mwuw:0,
    args:[subject:[type:np,oblig:yes,constraints:[sem:[hum]]],
      object:[type:np,oblig:yes,constraints:[case:acc, sem:[loc]]]]),
  ws(colo_practise,tr_cod,clause:[],mwuw:0,
    args:[subject:[type:np,oblig:yes,constraints:[sem:[hum]]],
      object:[type:np,oblig:yes,constraints:[case:acc, sem:[abstract]]]])]).
```

¶ 2. Quoniam qui agros colunt, ibidem **permanere** et **habitare** necessario debent, (qua in re populi agricolae a pastoribus distinguuntur); vel etiam quoniam loco, in quo habitamus, curam impendimus: factum est, ut colere ponatur saepissime pro habitare, quamvis aliquantulum ab ipso differat: *V. Homonym. in fin. Occurrit autem* -

a) Cum Accusativo loci. *Plaut. Aulul. prol.* 3. Hanc domum jam multos annos est cum possideo et colo. *Id. Bacch* 2. 2. 21. Colere regiones Acberunticas. *Cic. 2. Fam.* 12. 2. Urbem, urbem, mi Rufe, cole et in ista luce vive. *Forcellinus* recte hîc accepit *colere* pro frequentem et assiduum esse in loco aliquo; quod tamen idem est atque habitare. *Id. 2. Nat. Hecyr.* 3. 4. 33.; et *Cic.* 3. *Off.* 21. 82. pietatem. *Cic.* 5. *Verr.* 3. 6. pudorem et pudicitiam. *Plaut.* *Poen.* 5. 2. 137. quaestum suum. *Cic.* *Flacc.* 4. 9. religionem et fidem testimoniorum. Cf. *eumd.* *Fonteij.* 10. 21. *Plaut.* *Poen.* 4. 2. 7. servitum colere apud aliquem. *h. e.* servire. *Cic.* 3. *Herenn.* 3. 4. societates. *Id.* 5. *Fin.* 19. 50. et 3. *Fam.* 13. studia. *Id.* *Brut.* 91. 315. studium philosophiae. *Id.* 12. *Att.* 28. nec victum, nec vitam. *Id.* *fragm.* apud *Non.* 4. 280. *edit. vet.* victum lautum et elegantem. *Cic.* *Arch.* 7. 16. virtutem percipere et colere. *Plaut.* *Rud.* 1. 5. 25. vitam. *h. e.* agere, seu vivere. Adde *eumd.* *Trin.* 3. 2. 74. Sic *Ter. Heaut.* 1. 1. 84. vitam inopem colere. Adde *Cic.* 4. *Herenn.* 14. 21. et 12. *Att.* 28.; et *Virg.* 3. *G.* 532.

*Lexical world 1: {officium, aequum, bonum, affinitas, amicitia, amor, ars, aurum, beneficium, clientela, cognatio, fides, fortitudo, hospitium, ius, fas, lex, Mars, bellum, memoria, militia, mos, Musa, munus, pax, pietas, pudor, pudicitia, quaestus, religio, servitus, societas, studium}*

Perhaps we should isolate a lexical world to be associated with a multi-word unit :

*Lexical world 2: {aevum, aetas, vita, militia, victus}* : basis for a semi-open mwu : *vitam colere/agere* ? The decision depends on whether *militiam colere* is ambiguous with respect to *militia* as military service vs military spirit, with *colo* as spend/pass vs cultivate/cherish (see Lewis and Short)

## Colo in Lewis and Short

(the building of the relevant lexical worlds is left to the reader)

1. cōlo, colūi, cultum, 3, v. a. [from the [stem](#) KOΛ, whence βουκόλος, βουκολέω; cf.: [colonus](#), in-cola, agri-cola] (orig. pertaining to agriculture), *to cultivate, till, tend, take [care](#) of a field, garden, etc.* (freq. in all [per.](#) and [species](#) of composition).

### I. Prop. 1. A.

1. (α) With *acc.*: [fundum](#), Varr. R. R. 1, 1, 2: [agrum](#), id. ib. 1, 2, 14; Cato, R. R. 61; Col. 1 pr.: [agri non omnes frugiferi sunt qui coluntur](#), Cic. Tusc. 2, 5, 13; id. 2 (β) *Absol.*, Varr. R. R. 1, 2, 8; Verg. G. 1, 121; Dig. 19, 2, 54, § 1.

1. **B.** In gen., without reference to economics, *to abide, dwell, stay in a [place](#), to inhabit* (syn.: [incolo](#), [habito](#); most freq. since the Aug. [per.](#)).

1. (α) With *acc.*: [hanc domum](#), Plaut. Aul. prol. 4: [nemora atque cavos montes silvasque colebant](#), Lucr. 5, 955: [regiones Acherunticas](#), Plaut. Bacch. 2, 2, 21: [colitur ea pars \(urbis\) et habitatur frequentissime](#), Cic. Verr. 2, 4, 53, § 119: [urbem, urbem, mi Rufe, cole](#), id. Fam. 2, 12, 2: [has terras](#), id. N. D. 2, 66, 164; Tac. A. 2, 60: [loca Idae](#), Cat. 63, 70: [Idalium](#), id. 36, 12 sq.; 61, 17: [urbem Trojanam](#), Verg. A. 4, 343: [Sicaniam](#), Ov. M. 5, 495: [Maeoniam Sipylumque](#), id. ib. 6, 149: [Elin Messeniaque arva](#), id. ib. 2, 679: [regnum nemorale Dianae](#), id. ib. 14, 331: [hoc nemus](#), id. ib. 15, 545: [Elysium](#), Verg. A. 5, 735: [loca magna](#), Ov. M. 14, 681; Liv. 1, 7, 10: [Britanniam](#), Tac. Agr. 11: [Rheni ripam](#), id. G. 28: [victam ripam](#), id. A. 1, 59: [terras](#), id. ib. 2, 60; cf. id. H. 5, 2: [insulam](#), id. A. 12, 61; id. G. 29: [regionem](#), Curt. 7, 7, 4.

**Poet.**, of poets: [me juvat in primā coluisse Heliconā juventā](#), i. e. *to have written poetry in early youth*, Prop. 3 (4), 5, 19.

Also of animals: [anguis stagna](#), Verg. G. 3, 430; Ov. M. 2, 380.

2. (β) *Absol.*: [hic](#), Plaut. Ps. 1, 2, 68: [subdiu colere te usque perpetuom diem](#), id. Most. 3, 2, 78; Liv. 42, 67, 9; Curt. 9, 9, 2: [colunt discreti ac diversi](#), Tac. G. 16: [proximi Cattis Usipii ac Tencteri colunt](#), id. ib. 32: [circa utramque ripam Rhodani](#), Liv. 21, 26, 6: [quā Cilices maritimi colunt](#), id. 38, 18, 12: [prope Oceanum](#), id. 24, 49, 6: [usque ad Albim](#), Tac. A. 2, 41: [ultra Borysthenem fluvium](#), Gell. 9, 4, 6: [super Bosporum](#), Curt. 6, 2, 13: [extra urbem](#), App. M. 1, p. 111.

### II. Trop. (freq. and class.).

1. **A.** *To bestow [care](#) upon a thing, to [care](#) for.*

1. 1. Of the gods: [colere aliquem locum](#), *to frequent, cherish, [care](#) for, protect, be the guardian of*, said of [places](#) where they were worshipped, had temples, etc.: [deos deasque veneror, qui hanc urbem colunt](#), Plaut. Poen. 5, 1, 19; Cat. 36, 12: [Pallas, quas condidit arces, Ipsa colat](#), Verg. E. 2, 62: [ille \(Juppiter\) colit terras](#), id. ib. 3, 61; id. A. 1, 16 Forbig. *ad loc.*: [undis jura dabat, nymphisque colentibus undas](#), Ov. M. 1, 576: [urbem colentes di](#), Liv. 31, 30, 9; 5, 21, 3: [vos, Ceres mater ac Proserpina, precor, ceteri superi infernique di, qui hanc urbem colitis](#), id. 24, 39, 8: [divi divaeque, qui maria terrasque colitis](#), id. 29, 27, 1.
2. 2. Rarely with persons as object (syn.: [curo](#), [studeo](#), [observo](#), [obsequor](#)): [Juppiter, qui genus colis alisque hominum](#), Plaut. Poen. 5, 4, 24; cf.: [\(Castor et Pollux\) dum terras hominumque colunt genus](#), i. e. *improve, polish*, Hor. Ep. 2, 1, 7.
3. 3. Of the body or its parts, *to cultivate, attend to, dress, clothe, adorn, etc.*: [formamque augere colendo](#), *by attire, dress*, Ov. M. 10, 534: [corpora](#), id. A. A. 3, 107: [tu quoque dum coleris](#), id. ib. 3, 225.

With *abl.*: [lacertos auro](#), Curt. 8, 9, 21: [lacertum armillā aureā](#), Petr. 32: [capillos](#), Tib. 1, 6, 39; 1, 8, 9.

4. 4. With abstr. objects, *to cultivate, cherish, seek, practise, [devote](#) one's self to, etc.*; of mental and moral cultivation: [aequom et bonum](#), Plaut. Men. 4, 2, 10: [amicitiā](#), id. Cist. 1, 1, 27: [fidem rectumque](#), Ov. M. 1, 90: [fortitudinem](#), Curt. 10, 3, 9: [jus et fas](#), Liv. 27, 17 fin.: [memoriam alicujus](#),

- Cic. Fin. 2, 31, 101: bonos mores, Sall. C. 9, 1: suum quaestum colit, Plaut. Poen. 5, 2, 137: pietatem, id. As. 3, 1, 5; Ter. Hec. 3, 4, 33: virtutem, Cic. Arch. 7, 16; id. Off. 1, 41, 149: amicitiam, justitiam, liberalitatem, id. ib. 1, 2, 5: virginitatis amorem, Verg. A. 11, 584: pacem, Ov. M. 11, 297; cf. Martem, Sil. 8, 464: studium philosophiae, Cic. Brut. 91, 315: disciplinam, id. ib. 31, 117: aequabile et temperatum orationis genus, id. Off. 1, 1, 3: patrias artes militiamque, Ov. F. 2, 508; cf.: artes liberales, Suet. Tib. 60: ingenium singulari rerum militarium prudentiā, Vell. 2, 29, 5 Kritz.
5. 5. Of a period of time or a condition, *to live in, experience, live through, pass, spend*, etc.: servitutum apud aliquem, *to be a slave*, Plaut. Poen. 4, 2, 7: nunc plane nec ego victum, nec vitam illam colere possum, etc., Cic. Att. 12, 28, 2; and **poet.** in gen.: vitam or aevum = degere, *to take care of life*, for *to live*: vitam, Plaut. Trin. 3, 2, 74; id. Cas. 2, 1, 12; id. Rud. 1, 5, 25: vitam inopem, Ter. Heaut. 1, 1, 84: aevum vi, Lucr. 5, 1144 and 1149.
2. **B. Colere aliquem**, *to regard one with care*, i. e. *to honor, revere, reverence, worship*, etc. (syn.: obsequo, veneror, diligere).
1. 1. Most freq. of the reverence and worship of the gods, and the respect paid to objects pertaining thereto, *to honor, respect, revere, reverence, worship*: quid est enim cur deos ab hominibus colendos dicas? Cic. N. D. 1, 41, 115: hos deos et venerari et colere debemus, id. ib. 2, 28, 71; cf. id. ib. 1, 42, 119; id. Agr. 2, 35, 94; Liv. 39, 15, 2; Cat. 61, 48: Phoebe silvarumque potens Diana ... o colendi Semper et culti, Hor. C. S. 2 and 3; cf. Ov. M. 8, 350: deos aris, pulvinaribus, Plin. Pan. 11, 3: Mercurium, Caes. B. G. 6, 17: Apollinem nimiā religione, Curt. 4, 3, 21: Cererem secubitu, Ov. A. 3, 10, 16: (deam) magis officiis quam probitate, id. P. 3, 1, 76: per flamines et sacerdotes, Tac. A. 1, 10; Suet. Vit. 1: quo cognomine is deus quādam in parte urbis colebatur, id. Aug. 70: deum precibus, Sen. Herc. Oet. 580: testimoniorum religionem et fidem, Cic. Fl. 4, 9; cf. id. Font. 10, 21; and: colebantur religiones pie magis quam magnifice, Liv. 3, 57, 7; and: apud quos juxta divinas religiones humana fides colitur, id. 9, 9, 4: sacra, Ov. M. 4, 32; 15, 679: aras, id. ib. 3, 733; 6, 208; cf. Liv. 1, 7, 10; Suet. Vit. 2 et saep.: numina alicujus, Verg. G. 1, 30: templum, id. A. 4, 458; Ov. M. 11, 578: caerimoniae sepulcrorum tantā curā, Cic. Tusc. 1, 12, 27: sacrarium summā caerimoniā, Nep. Th. 8, 4: simulacrum, Suet. Galb. 4.
2. 2. Of the honor bestowed upon men: ut Africanum ut deum coleret Laelius, Cic. Rep. 1, 12, 18: quia me colitis et magnificatis, Plaut. Cist. 1, 1, 23; Ter. Ad. 3, 2, 54: a quibus diligenter observari videmur et coli, Cic. Mur. 34, 70; cf. id. Fam. 6, 10, 7; 13, 22, 1; id. Off. 1, 41, 149; Sall. J. 10, 8: poëtarum nomen, Cic. Arch. 11, 27: civitatem, id. Fl. 22, 52; cf.: in amicis et diligendis et colendis, id. Lael. 22, 85 and 82: semper ego plebem Romanam militiae domique ... colo atque colui, Liv. 7, 32, 16: colere et ornare, Cic. Fam. 5, 8, 2: me diligentissime, id. ib. 13, 25 init.: si te colo, Sexte, non amabo, Mart. 2, 55: aliquem donis, Liv. 31, 43, 7: litteris, Nep. Att. 20, 4: nec illos arte colam, nec<sup>16</sup> opulenter, Sall. J. 85, 34 Kritz.

2. **cōlo**, āvi, ātum, āre, v. a. [colum], *to filter, strain, to clarify, purify* (post-Aug.): ceram, Col. 9, 16, 1: mel, id. 12, 11, 1: vinum sportā palmeā, Pall. Febr. 27: sucum linteum, Plin. 25, 13, 103, § 164: thymum cribro, Col. 7, 8, 7: aliquid per linteum, Scrib. Comp. 271: ad colum, Veg. 2, 28, 19: per colum, Apic. 4, 2: aurum, App. Flor. p. 343, 20: terra colans, Plin. 31, 3, 23, § 38: faex colata, id. 31, 8, 44, § 95.

**Poet.**: amnes inductis retibus, i. e. *to spread out a fish-net*, Manil. 5, 193.

Depending on the level of granularity that is deemed adequate for the parser, the number of word senses associated with a lexeme will vary, and so will the number of lexical worlds that will help to discriminate between the various word senses. The entries for *colo* in Lewis and Short offer a nice playground for lexical world building : clearly two lexemes (*colo, colare* vs *colo, colere*). *Colo, colare* does not need lexical world building, since only one word sense is offered. For *colo, colere* the granularity level is open to discussion. How many word senses, which items to include in the lexical world associated with each word sense ? Should we distinguish between lexical worlds derived from definitions and lexical worlds derived from citations (when the definitions are provided in the language described, as is the case in Forcellini) ?

Should a lexical world be made out of word-forms or their corresponding lexemes ?

Which items should be regarded as stopwords ? Function words, very high frequency items, lexicographic place holders (*res* etc.), ...

How do we measure the distance between the head of an argument filler in the sentence to be parsed and what we find as possible fillers in the dictionaries (the situation we have with *ripam* as filler of

16 According to modern editions the citation ought to run : *neque illos arte colam, me opulenter*

the object arg in our sentence *Liceat nobis vobisque utramque **ripam** colere* and at the same time occurring in the dictionary entry in the same syntactic position— as is the case in both Forcellini and Lewis and Short – is of course due to the fact that the text we are parsing is found in a work that is a primary source for dictionary citations). When we do not find the item occurring as such in the dictionary sources (that is, if we found neither *ripam* nor *ripa* (the corresponding lexeme) in our sources), we have to find a way of selecting the right lexical world for our argument, that is measure the distance between *ripa* and the fillers of the arg position in the dictionary sources ; if we are unable to determine the position filled by the members of the lexical world, we can still use lexical distance to determine the word sense to be selected, although the degree of accuracy is likely to be less.

Lexical distance can be measured with a sufficient degree of accuracy for English because of the quality and number of lexicographical resources that can be called into play (see Michiels 2016b). For Latin we will have to rely on cooccurrence of items in *definitions* (if given in Latin) and *citations*, i.e. in lexical worlds. The process may look strange, but I think it is worth trying because lexicographical resources are much denser than other textual resources.

To make things clearer, what I'm claiming is that if we establish lexical worlds such as the one I listed above : {*domus, regio, urbs, terra, nemus, mons, silva, locus, Elysium, arvum, rus, **ripa**, Helicon, stagnum, flumen*} then the claim is that, for instance, *urbs* and *terra* are related because they cooccur in this particular lexical world. Their relatedness would be computed on the number of times they cooccur in the whole set of lexical worlds derived from the lexicographical resources we exploit. If we build lemmatised lexical worlds, we gain in density but introduce a source of error due to wrong lemmatisation.

I leave such issues as food for thought and leave the floor to Copilot...always keen to agree with whoever it happens to be talking to...

## ***A Conversation With Copilot 6 Feb 2025***

*If I give you the two Latin sentences 'Colunt agros' and 'Colunt deos' how do you go about selecting the right reading for 'colunt' ?*

In Latin, the verb 'colunt' can mean 'they cultivate' or 'they worship', and the correct interpretation often depends on the context provided by the surrounding words.

### **1. Colunt agros:**

- 'Agros' means 'fields' or 'lands'.
- It makes sense to interpret 'colunt' as 'they cultivate'. So, the sentence translates to 'They cultivate the fields'.

### **2. Colunt deos:**

- 'Deos' means 'gods'.
- Here, 'colunt' is better understood as 'they worship'. Thus, the sentence translates to 'They worship the gods'.

In essence, examining the objects ('agros' and 'deos') guides the correct reading of 'colunt'. Is there anything else you'd like to explore or learn about Latin? ?

*Does that mean you rely on English to select the right readings of a Latin verb?*

That's an interesting question! When I interpret Latin, or any language, I'm not relying on English as a crutch. Instead, I use the context within the Latin sentences themselves to determine the correct meaning. So, for 'colunt agros' and 'colunt deos', the nouns 'agros' and 'deos' provide the necessary context to select the right reading of 'colunt'.

In Latin, as with many languages, context is key. Words can have multiple meanings, and understanding the surrounding text is essential to making accurate interpretations. It's the beauty of language that a single word can carry different shades of meaning depending on its use.

Would you like to dive deeper into Latin grammar or explore another topic? ?

*If you use the context of the Latin verb colunt in colunt agros and colunt deos, that means that you can establish how many meanings colo has, and how to keep them apart.*

Exactly! Let's break it down:

The verb **colō, colere, coluī, cultus** has several meanings, and context is key to selecting the right one. Here are some common meanings of 'colō':

**1. To cultivate or till the land:**

- Example: *Agricola agrum colit.* (The farmer cultivates the field.)

**2. To inhabit or dwell in:**

- Example: *Rōmānī urbem colunt.* (The Romans inhabit the city.)

**3. To worship or honor:**

- Example: *Antīquī deōs colēbant.* (The ancients worshipped the gods.)

**4. To care for or nurture:**

- Example: *Flōrēs in hortō coluntur.* (The flowers in the garden are nurtured.)

In your examples, the nouns 'agros' and 'deos' guide the interpretation:

- **Colunt agros:** 'Agros' (fields) implies 'cultivate' → 'They cultivate the fields.'
- **Colunt deos:** 'Deos' (gods) implies 'worship' → 'They worship the gods.'

By understanding the various meanings of 'colō' and considering the context provided by the nouns, we can accurately interpret the verb's meaning in different sentences. If you'd like to explore more Latin verbs or have any other questions, feel free to ask! ?

*The Latin examples you give are translations of corresponding English sentences. You cannot deny that you use English, and not Latin, to establish which is the correct word sense of colo in context.*

I understand your point. When providing explanations, I use English to make the information accessible and clear. However, the process of determining the correct meaning of a Latin word like 'colō' is rooted in Latin grammar and syntax, not in English.

When I interpret Latin sentences, I analyze the Latin words and their relationships to each other within the sentence. The context provided by the nouns 'agros' (fields) and 'deos' (gods) directly informs the appropriate sense of 'colō'. English translations are used for clarity and communication with you, but the actual determination of meaning relies on understanding the Latin language and its nuances.

Would you like to explore more about Latin language, its grammar, or any other topic? ?

*This means you rely on lexicographical data to be found in such dictionaries as Forcellini or Lewis and Short?*

Absolutely! Lexicographical resources like the Forcellini and Lewis and Short dictionaries are invaluable for understanding the various meanings and usages of Latin words. These comprehensive dictionaries provide definitions, examples, and contexts that are essential for accurate interpretation and translation.

When determining the correct sense of a word like 'colō', such dictionaries offer detailed entries that outline the different meanings based on historical and literary contexts. By leveraging this rich lexical data, I can more accurately interpret Latin texts and provide appropriate translations.

Would you like to explore specific entries from these dictionaries or delve into another aspect of Latin language and literature? ?

*well, the Forcellini entry for colo is a good starting point. How do you go about sorting the fillers for the object position?*

Great! Let's take the Forcellini entry for "colō" as our foundation. When it comes to sorting fillers (i.e., objects) for the verb "colō" based on its various meanings, we can follow these steps:

1. **Identify Possible Meanings:** Review the Forcellini entry to list the various meanings of "colō," such as cultivating, inhabiting, worshiping, caring for, etc.
2. **Group Objects by Meaning:** For each meaning, identify common objects that fit logically. For example:
  - **Cultivating (agricultural context):** Fields (agros), land (terram), vineyards (vīneās), gardens (hortos)
  - **Inhabiting (dwelling context):** City (urbem), house (domum), region (regiōnem)
  - **Worshiping (religious context):** Gods (deōs), shrines (fanōs), temples (templum)
  - **Caring for (nurturing context):** Children (liberōs), plants (plantae), animals (animālia)
3. **Consider Context:** Determine the likely context of the sentence based on the surrounding words and overall theme. For example, if the sentence mentions agricultural activities, focus on objects related to cultivation.
4. **Choose the Appropriate Object:** Select the object that best aligns with the intended meaning of "colō" in the given context.

By following these steps, we can accurately sort and choose the appropriate objects for "colō" based on its meanings. If you have a specific sentence or context in mind, we can apply this process together! ?

*Yes, I am interested in how you compute lexical distance between an item in a text (colo ripam) and the fillers for the relevant syntactic position in the lexicographic data. No problem, by the way, for ripam, which appears in a Forcellini or Lewis and Short example. But if the object does not appear as such, the computing of lexical distance is a must, or have I got it wrong?*

You've got it right! Computing lexical distance can be a crucial step when an object doesn't appear explicitly in lexicographical examples. Here's how the process might work:

1. **Identify Contextual Meaning:** Analyze the sentence 'colō ripam' to understand the overall context. Here, 'ripam' (bank, shore) suggests a possible action related to caring for or maintaining the bank/shore.
2. **Lexicographical Data:** Gather all possible meanings of 'colō' from resources like Forcellini or Lewis and Short.
3. **Lexical Distance Calculation:**
  - **Semantic Similarity:** Use semantic similarity measures to compare the meaning of 'ripam' with known objects of 'colō'. Tools like WordNet or other lexical databases can help quantify the similarity between words.
  - **Contextual Analysis:** Look for occurrences of 'ripam' in similar contexts or related literature to infer its appropriate meaning.
4. **Rank Potential Meanings:** Based on the lexical distance and contextual analysis, rank the potential meanings of 'colō' from most to least likely.
5. **Select the Best Fit:** Choose the meaning of 'colō' that has the closest lexical distance and makes the most sense in the given context.

In the case of 'colō ripam', if 'ripam' is not explicitly listed in the dictionaries, computing lexical distance helps identify that 'colō' could mean something akin to maintaining or caring for the bank/shore, drawing parallels with other objects like fields, gardens, or even shrines, depending on the context.

This process ensures accurate interpretation even when explicit examples are missing.

In the case of *colo* the specifications so far (i.e in the present version of ALP) are in terms of **semantic features**, whose hierarchy is explored by the feature unification algorithm, so that hyponymy is taken into account (we are asking for a dog, we are given a poodle, OK ; we are asking for a poodle, we are given a dog, noway).

## **More on selectional restrictions**

In a sentence such as *Ille sapientissimus vir Ithacam ut videret immortalitatem scribitur repudiasse*, we should realize that inserting commas around *Ithacam ut videret* amounts to guiding the parsing; as a matter of fact, it can be seen as a first, important step in parsing the sentence. But we should try to do without such commas, as they do not belong to the text but were introduced at various points in time by editors, sometimes in a way that reflects usage in one of our modern languages, such as the comma we find following *vereor* and preceding *ne* in the Budé edition of the *De Amicitia*, 14, which is more appropriate to German than to French, the language of Combès himself:

*Quocirca maerere hoc eius eventu uereor, ne inuidi magis quam amici sit.* (edited by Robert Combès, Paris, 1971)

Here too selectional restrictions are essential. Not only to discriminate between *repudiare* as *reject* and *repudiare* as *repudiate*, but to help the parser assign *ithacam* as object of *videret* and *immortalitatem* as object of *repudiasse*.

The two readings of *repudiare* place different selectional restrictions on the object:

```
% REPUDIARE
lexarg(repudiare,
      arglist:[ws(repudio1_reject,tr_cod,clause:[],mwuw:0,
        args:[subject:[type:np,oblig:yes,constraints:[sem:[hum]]],

## Appendix IV Grammatical syncretism or structural ambiguity?

Let's consider Tacitus Hist. I 79 1:

*conuersis ad ciuile bellum animis externa sine cura habebantur*

The punctuation we are going to insert is not innocent:

*Conuersis ad ciuile bellum animis, externa sine cura habebantur.*

With the marking of the sentence boundaries and its division by means of the comma, the interpretation of *conuersis ad ciuile bellum animis* as an ablative absolute is strongly suggested. This is the text proposed among others by Bornecque, and his translation (inspired by Burnouf's) conforms to this interpretation, which splits the sentence in two:

*Les esprits tournés à la guerre civile, les questions extérieures étaient négligées.*

The link between the two parts of the sentence is left to inference, a process of interpretation that is known to be both universal and automatic. As Lavency is right to point out in VSVS, the ablative absolute describes a situation concomitant with the process indicated in the main clause. It is the inference that gives this concomitance the possibility of being tinged with the semantic and discursive value that completes its insertion into the sentence.

A look at Burnouf's translation confirms that it was reworked by Bornecque. Burnouf translated:

*Les esprits tournés à la guerre civile ne songeaient plus aux dangers du dehors.*

Here the statement is a single block, and the link between the two parts is not left to inference but embodied in the subject-verb relationship.

Goelzer goes even further in integrating the two parts. He interprets *externa* as an epithet, the *bella* it modifies being easily deduced from the *bellum* of the first part<sup>17</sup>:

*Les esprits tournés à la guerre civile n'avaient plus souci des guerres étrangères;*

Note the semicolon closing the sentence. What follows is indeed the relation of a Sarmatian attack in Moesia, an act of war:

*conuersis ad ciuile bellum animis externa sine cura habebantur eo audentius rhoxolani sarmatica gens priore hieme caesis duabus cohortibus magna spe moesiam intruperant ad nouem milia equitum ex ferocia et successu praedae magis quam pugnae intenta*

If *conuersis ad ciuile bellum animis* is not an ablative absolute, how should it be analyzed? It can be parsed as an agent of *sine cura habebantur*, with *animis* not requiring a preposition to play this role.

Tacitus did not intend to accompany his text with syntax trees that would show us the reading he had in mind at the time of writing. We know his taste for the ablative absolute. He may very well have started with an ablative absolute and continued with an agent, thus becoming guilty (or enriching his text) of grammatical syncretism.

It is interesting to note that ALP retains both analyses, judging them in accordance with the grammar on which its parsing algorithm is based. According to the weighting system that favors arguments over satellites (such as circumstantial elements and ablative absolutes), the analysis of

---

<sup>17</sup> ALP is not sophisticated enough to take into account the analysis of *externa* as an adjective modifying an implied *bella*. It considers *externis* as the ablative of a substantivized neuter plural adjective, *externa*, which is encountered in Tacitus in the same way as the non-substantivized adjective *externus*. It seems preferable to consider *externa* as substantivized with the meaning of 'what concerns the outside,' 'external affairs.' Indeed, war is not neglected; the response to the Sarmatian attack is decisive and strong, but it is the climate of indifference towards what is not Rome or Italy that provided the Sarmatians with an opportunity for war. I propose: *Les esprits préoccupés par la guerre civile n'avaient cure des affaires extérieures.*

*conuersis animis* as an agent is preferred to the analysis that makes it an ablative absolute.

Let's consider a second example, where the interpretation of the sequence as an ablative absolute stretches the links even more, although the inference proves powerful enough to tighten the links that grammatical analysis has loosened. This example is also taken from Tacitus' Histories,

Tacitus Hist. III 41 : *missis ad uitellium litteris auxilium postulat*

Here too, Bornecque splits the sentence into two, and reads the first part as an ablative absolute:

*Missis ad Vitellium litteris, auxilium postulat.*

And here too, he translates (or rather borrows Burnouf's translation verbatim) into a two-part statement, joined by the coordinating conjunction *et*:

*Il écrit à Vitellius et lui demande du secours.*

A coherence-preserving inference ensures that the reader does not imagine that writing the letter and requesting aid are two separate actions (with the coordination being interpreted as marking chronological succession, a quite powerful inference in other contexts).

This of course gives a rather loose translation, similar to Goelzer's, who nevertheless proposes a text without a comma:

*Missis ad Vitellium litteris auxilium postulat.*

*Il envoie un message à Vitellius et lui réclame du renfort.*

If we free ourselves from reading *missis litteris* as an ablative absolute, we will have fewer scruples proposing a more concise translation:

*Il écrit à Vitellius pour lui réclamer du renfort.*

*Par lettre il réclame à Vitellius des renforts.*

This is along the lines of a standard translation into English:

*He wrote to Vitellius asking for aid.* (Complete Works of Tacitus. Tr. Alfred John Church and William Jackson Brodribb 1873)

Here, the alternative analysis makes *missis litteris* an ablative indicating means. The *missis* might then appear somewhat superfluous, not in line with the search for brevity that characterizes our author. Another case of syncretism? ALP provides both analyses, giving them equal weight, as they both make *missis litteris* a satellite and not an argument (circumstantial indicating means or ablative absolute).

litteris

It is to be noted that in the Histories there are clear examples of *litteris* as an ablative of means:

*Flaccus omisit inceptum aliisque litteris Gallum monuit ne terreret abeuntis* 4,19

*profectus eadem nocte Flavianus obuiis Vespasiani litteris discrimini exemptus est* 3,10

Likewise, we find *missis* ... *litteris* as an ablative absolute:

*missis sane ad eum Primi Antonii litteris* 4,13 (the *ad eum* is decisive in the analysis as an ablative absolute).

The way is thus open to an analysis of our examples that leans to one side or the other, or maintains itself in the middle. We do not think that the latter analysis, open to syntactic syncretism, should be dismissed outright. A parser such as ALP has the merit of showing us where a given grammar leads us.

It should be clearly stated that this syncretism is a product of analysis, and not a linguistic given. There are only texts and interpretations, both intimately linked, since interpretation is based on texts, and texts are established in accordance with interpretations, which in turn materialize through translations, which are themselves subject to an interpretation procedure: one cannot escape the prison of language.

Lavency 2002, grappling with the phenomenon we examine here, speaks of 'double analyses' and 'uncertainties of analysis.' This is the analytical point of view. The syncretic option is that of interpretation.

Note in passing that one of the examples given by Lavency to illustrate this uncertainty is rather curious:

*Id Helvetii ratibus ac lintribus iunctis transibant* (Caesar, B.G. I, 12).

Lavency writes: The expression *flumen ratibus ac lintribus iunctis transire* (cf. Caes., G. II, 12, 1) is read as an Ablative of Modality (hoc modo) insofar as *iunctis*, considered omissible, is interpreted as an epithet participle. Read as a necessary element, the whole is considered as an Ablative absolute.

However, it would seem that *iunctis* can only be associated with *lintribus* (it is a pontoon bridge), and not with the whole *ratibus ac lintribus*<sup>18</sup>. The omissibility of *iunctis* is therefore purely grammatical and not semantic. Certainly, for it to be an ablative absolute, *iunctis* is necessary. But this ablative absolute would be coordinated with an ablative of means, which is extremely unlikely in a text written by Caesar. I believe that what came into play here is the almost automatic association in the grammarian's mind of the NP+pp couple in the ablative with the possibility of viewing the constituent as an ablative absolute.

It should be noted that once a past participle comes into play, it is likely to have under its dependency the entire actantial system of its predicate, whatever the local role played by the participle. In the second example of analytical uncertainty involving an ablative absolute proposed by Lavency, namely:

*Cuius aduentu spe inlata militibus ac redintegrato animo cum pro se quisque in conspectu*

---

18 The translations are in agreement: Les Helvètes la passaient sur des radeaux et sur des barques jointes ensemble. (Artaud)  
Les Helvètes étaient en train de la franchir à l'aide de radeaux et de barques assemblées. (Constans)  
Les Helvètes la traversaient sur des radeaux et sur un pont de bateaux.

*imperatoris etiam extremis suis rebus operam nauare cuperet paulum hostium impetus tardatus est.*  
(Caesar, B.G. II, 25, 3),

about which Laveney writes: During the critical episode of the battle against the Nervii, Caesar advances to the front line: *cuius aduentu spe inlata militibus... paulum hostium impetus tardatus est* (Caes., G. II, 25, 3). The arrival of Caesar can be considered as the moment of morale restoration (paradigm *hoc tempore*); an admirer of Caesar might choose another reading (paradigm *ea re + passive*) and see in it the source of the Roman resurgence. Read together with its two components, *spe inlata* is undoubtedly spontaneously interpreted as an ablative absolute and as referring to the framework in which the pressure exerted by the enemy is released.

I believe that the same analysis automatism (GN ablative + pp -> Abl. Absolute) came into play. An analysis where the grammatical links are tighter (an agent complement of *tardatus est*, with two components, *spe inlata* and *redintegrato animo*, the participles *inlata* and *redintegrato* having their own agent, *cuius aduentu*) seems more plausible to me. But in the syncretic perspective that I am arguing for here, reading *spe inlata* and *redintegrato animo* (*inlata* and *redintegrato* sharing the agent *cuius aduentu*) as a coordinated ablative absolute and explained by the subordinate clause in *cum* (which develops the consequence), is concurrent, in the etymological sense of the word.

Grammatical syncretism is likely to lead to endless (but hopefully fruitful) discussion. I offer the following as food for thought.

The noun *dolor* welcomes as argument (optional arg, as are most noun args) a non-finite clause of the accusative-cum-infinitive type :

*Qua quidem ex re magnum accipio dolorem, homines amplissimis populi Romani beneficiis usos L.Pisonem ducem optimae sententiae non secutos.* Cic Phil 1 14

The predicate *ango* (at least passive *angor*) can have the same type of arg :

*Equidem angor animo non consili, non ingeni, non auctoritatis armis egere rem publicam* Cic Br 7

Remaining with the same author, how are we to account for :

*Nullus dolor me angit unum omnia posse.* Cic Att 4 18 2

Shall we parse *unum omnia posse* as noun arg of *dolor* or verb arg of *angit* ?

The answer depends on the acceptability rating of

*Unum omnia posse me angit* / *Me angit unum omnia posse.*

But we do not have access to such acceptability ratings for a language that no longer has any native speaker.

Or have we got another case of grammatical syncretism ? *Unum omnia posse* would then be the source of the (here denied) mixture of anxiety and indignation, or rather both the source and the contents of such a feeling. It would then have to be parsed as a doubly bound arg with a double semantic import.

While learning Latin, we are very likely to have come across the much quoted example from Livy, which happens to be included in ALP's secondary test file :

*Angebant ingentis spiritus virum Sicilia Sardiniaque amissae.*

We were told that the two islands couldn't be the source of Hamilcar's anxiety – it was their loss that upset him. But notice that here the anxiety source (and its contents) is in *subject* position with respect to the predicate *angebant*.

This is a good argument in favour of regarding *dolor* + its arg as subject of *angit* in

*Nullus dolor me angit unum omnia posse.*

If we consider the active to passive transformation to be applicable to *ango* in the standard way, we should be able to look for passive clauses in which there is an Abl arg corresponding to the subjects of the active clauses, along the lines of :

*Vir ingentis spriritus amissis Sicilia Sardiniaque angebatur.*

which I suppose we won't find (when we do find an ablative it is generally *animo*, which redundantly specifies the 'location' of the feeling of anguish).

A look at French may be helpful :

*L'idée de la mort l'angoissait -->*

- a) *Il était angoissé par l'idée de la mort.*
- b) *Il était angoissé à l'idée de la mort.*

Latin has b-like clauses. How are we to parse *à l'idée de la mort* in b ? I suggest we parse it the way we parse the infinitive-cum-accusative argument in the Latin sentences.

## Appendix V Word Order

General Principle: The strength of the links that unite two elements in an utterance tends to bring them closer together.

Elements linked to varying degrees may find themselves more or less distant from each other. A whole range of factors come into play: expressiveness, metrics, search for originality or, on the contrary, imitation, etc. And it can be noted that the closer the link between two elements, the more they can be kept apart for the reasons we have just mentioned ; see here the counterpart (and in fact confirmation) of the general principle stated above.

This distance is, however, controlled (kept within certain limits) by the requirement of computability, the necessity for existing links to remain retrievable.

Such computability also depends on numerous factors. If the link is very close (for example, participation in the same phraseological unit), it will more easily resist the tension created by distance, as mentioned above. The closeness of the links also depends on participation in actantial structures as well as membership in semantic or pragmatic sets. Lexicographical resources are essential for the establishment of such sets.

Another very important factor is the quality of the marking of relations. Elements that are not likely to offer a range of morphological analyses (e.g. two plural genitives) will be more easily identifiable as elements of the same constituent. The power of marking will depend on its ability to distinguish an element from its environment, making it 'stand out'.

Just as grammaticality is measured by the degree of conformity to a grammar (itself derived, essentially through distributive analysis, from a corpus of presumed 'standard', i.e. non-deviant, utterances), computability is assessed by a plausibility index assigned to an analysis developed on the basis of the grammaticality of the utterance and the tensions that the links postulated by the grammatical analysis may have undergone.

It is thus conceivable to account for word order by establishing (computational aspect of computability) a balance between strength of link, distance, and marking quality. Analyses suggested by a grammatical module coupled with a lexicon will be weighted according to the results of this computation. This is the approach that ALP attempts to implement.

Studies of word order based on distributional statistics that take into account neither quality of marking nor strength of link are likely to prove meaningless.
